1 Compilation and installation of the Sollya tool

1.1 Compilation dependencies

The Sollya distribution can be compiled and installed using the usual ./configure, make, make install procedure. Besides a C compiler, Sollya needs the following software libraries and tools to be installed. The ./configure script checks for the installation of the libraries. However Sollya will build without error if some of its external tools is not installed. In this case an error will be produced at runtime.

- GMP
- MPFR
- MPFI
- fplll
- libxml2
- gnuplot

The use of the external tool rlwrap is highly recommended but not indispensable. Use the -A options of rlwrap for correctly displayed ANSI X3.64/ ISO/IEC 6429 colored prompts (see below).

1.2 Sollya command line options

In principle Sollya reads all its input on standard input and responds on standard output. Reading of files is internally supported but no file names can be given for input when the tool is started. Remark that it is nevertheless possible to use Sollya on input contained in a file; just redirect standard input to the file, writing on bash for example:

```bash
~/% sollya < myfile.sollya
```

All configurations of the internal state of the tool are done by commands given on the Sollya prompt. Nevertheless, some command line options are supported; they work at a very basic I/O-level and can therefore not be implemented as commands.

The following options are supported when calling Sollya:

- --nocolor: Sollya supports coloring of the output using ANSI X3.64/ ISO/IEC 6429 escape sequences. Coloring is deactivated when Sollya is connected on standard input to a file that is not a terminal. This option forces the deactivation of ANSI coloring. This might be necessary on very old grey-scale terminals or when encountering problems with old versions of rlwrap.

- --noprompt: Sollya prints a prompt symbol when connected on standard input to a pseudo-file that is a terminal. The option deactivates the prompt.

- --oldrlwrapcompatible: This option is deprecated. It makes Sollya emit a wrong coloring escape sequence for making it compatible with versions of rlwrap that do not support the -A option. The option is considered as a hack since it is known to garble the output of the tool under some particular circumstances.

- --help: Prints help on the usage of the tool and quits.
2 Introduction

Sollya is an interactive tool for handling numerical functions and working with arbitrary precision. It can evaluate functions accurately, compute polynomial approximations of functions, automatically implement polynomials for use in math libraries, plot functions, compute infinite norms, etc. The language Sollya comes with is a full-featured script programming language with support for procedures etc.

Let us begin this manual with an example. Sollya does not allow command line edition; since that may quickly become uncomfortable, we highly suggest to use the software rlwrap with Sollya:

```
~/% rlwrap sollya
```

Sollya manipulates only functions in one variable. The first time that an unbound variable is used, this name is fixed. It will be used to refer to the free variable. For instance, try

```
> f = sin(x)/x;
> g = cos(y)-1;
```

Warning: the identifier "y" is neither assigned to, nor bound to a library function nor external procedure, nor equal to the current free variable. Will interpret "y" as "x".

```
> g;
```

```
cos(x) - 1
```

Now, the name \textit{x} can only be used to refer to the free variable:

```
> x = 3;
```

Warning: the identifier "x" is already bound to the free variable, to a library function or to an external procedure. The command will have no effect.

```
> x = 3;
```

Warning: the last assignment will have no effect.

If you really want to unbound \textit{x}, you can use the \texttt{rename} command and change the name of the free variable:

```
> rename(x,y);
```

Information: the free variable has been renamed from "x" to "y".

```
> g;
```

```
cos(y) - 1
```

```
> x=3;
```

```
> x;
```

```
3
```

As you have seen, you can name functions and easily work with. The basic thing to do with a function is to evaluate it at some point:

```
> f(-2);
```

Warning: rounding has happened. The value displayed is a faithful rounding of the true result.

```
0.45464871341284084769800093295587242135112748572394
```

```
> evaluate(f,-2);
```

```
0.45464871341284084769800093295587242135112748572394
```

The printed value is generally a faithful rounding of the exact value at the working precision. The working precision is controlled by the global variable \texttt{prec}:
Sometimes, a faithful rounding cannot easily be computed. In such a case, an approximated value is printed:

```
> sin(pi);
Warning: rounding has happened. The value displayed is *NOT* a faithful rounding of the true result.
2.370282108802210278292237916205884206827316800332031959797e-15413
```

The philosophy of Sollya is: whenever something is not exact, print a warning. This explains the warnings in the previous examples. If the result can be shown to be exact, there is no warning:

```
> sin(0);
0
```

Let us finish this Section with a small complete example that shows a bit of what can be done with Sollya:

```
> restart;
The tool has been restarted.
> prec=50;
The precision has been set to 50 bits.
> f=cos(2*exp(x));
> d=-[1/8;1/8];
> p=remez(f,2,d);
> derivativeZeros = dirtyfindzeros(diff(p-f),d);
> derivativeZeros = inf(d)..:derivativeZeros:.sup(d);
> max=0;
> for t in derivativeZeros do {
>   r = evaluate(abs(p-f), t);
>   if r > max then { max=r; argmax=t; };
> }
> print("The infinite norm of", p-f, "is", max, "and is reached at", argmax);
The infinite norm of -0.416265572875373 + x * (-1.798067209218835 + x * (-3.89710727747639e-2)) - cos(2 * exp(x)) is 8.630659443624325e-4 and is reached at -5.801672331417684e-2
```

In this example, we define a function \( f \), an interval \( d \) and we compute the best degree-4 polynomial approximation of \( f \) on \( d \) with respect to the infinite norm. In other words, \( \max_{x \in d} \| p(x) - f(x) \| \) is minimal amongst polynomials with degree not greater than 4. Then, we compute the list of the zeros of the derivative of \( p - f \) and add the bounds of \( d \) to this list. Finally, we evaluate \( |p - f| \) for each point in the list and store the maximum and the point where it is reached. We conclude by printing the result in a formatted way.

Note that you do not really need to use such a script for computing infinite norm; as we will see, the command `dirtyinfnorm` does this for you.
3 General principles

The first goal of Sollya is to help people to use numerical functions and numerical algorithms in a safe way. It is first designed to be used interactively but it can also be used in scripts.

One of the particularities of Sollya is to work with multi-precision arithmetic (it uses the MPFR library). For safety purposes, Sollya knows how to use interval arithmetic. It uses the interval arithmetic to produce tight and safe results with the precision required by the user.

The general philosophy of Sollya is: 

When you can make a computation exactly and sufficiently quickly, do it; when you cannot, do not, unless you have been explicitly asked for.

The precision of the tools is set by the global variable prec. It indicates the number of bits used to represent the constants in Sollya. In general, the variable prec determines the precision of the outputs of commands: more precisely, the command will internally determine what precision should be used during the computations in order to ensure that the output is a faithfully rounded result with prec bits.

For decidability and efficiency reasons, this general principle cannot be applied every time, so be careful. Moreover certain commands are known to be unsafe: they give in general excellent results and give almost prec correct bits in output for everyday examples. However they are just heuristic and should not be used when the result must be safe. See the documentation of each command to know precisely how confident you can be with its result.

A second principle (that comes together with the first one) is: 

When a computation leads to inexact results, inform the user by a warning. This can be quite irritating in some circumstances: in particular if you are using Sollya within other scripts. The global variable verbosity lets you change the level of verbosity of Sollya. When set to 0, Sollya becomes completely silent on stdout and prints only very important messages on stderr. Increase verbosity if you want more information about what Sollya is doing. Note that when you affect a value to a global variable, a message is always printed even if verbosity is set to 0. In order to silently affect a global variable, use !:

```
> prec=30;
The precision has been set to 30 bits.
> prec=30!;
```

For conviviality reasons, values are displayed in decimal by default. This lets a normal human being understand the numbers he or she manipulates. But since constants are internally represented in binary, this causes permanent conversions that are sources of roundings. Thus you are loosing in accuracy and Sollya is always complaining about inexact results. If you just want to store or communicate your results (to another tools for instance) you can use bit-exact representations available in Sollya. The global variable display defines the way constants are displayed. Here is an example of the five available modes:

1Remark: some of the behaviors of Sollya slightly change when used in scripts. For example, no prompt is printed.
Remark that it is possible to maintain the general verbosity level at some higher setting while deactivating all warnings on roundings. This feature is controlled using the \texttt{roundingwarnings} global variable. It may be set to \texttt{on} or \texttt{off}. By default, the warnings are activated (\texttt{roundingwarnings = on}) when \texttt{Sollya} is connected on standard input to a pseudo-file that represents a terminal. They are deactivated when \texttt{Sollya} is connected on standard input to a real file. See \texttt{8.134} for further details; the behavior is illustrated with examples there.

As always, the symbol $e$ means $\times 10^\square$. The same way the symbol $b$ means $\times 2^\square$. The symbol $p$ means $\times 16^\square$ and is used only with the $0x$ prefix. The prefix $0x$ indicates that the digits of the following number until a symbol $p$ or white-space are hexadecimal. The suffix $2$ indicates to \texttt{Sollya} that the previous number has been written in binary. \texttt{Sollya} can parse these notations even if you are not in the corresponding \texttt{display} mode, so you can always use them.

You can also use memory-dump hexadecimal notation frequently used to represent IEEE 754 \texttt{double} and \texttt{single} precision numbers. Since this notation does not allow for exactly representing numbers with arbitrary precision, there is no corresponding \texttt{display} mode. However, the commands \texttt{printhexa} respectively \texttt{printfloat} round the value to the nearest \texttt{double} respectively \texttt{single}. The number is then printed in hexadecimal as the integer number corresponding to the memory representation of the IEEE 754 \texttt{double} or \texttt{single} number:

\begin{verbatim}
> printhexa(a);
0x4031400000000000
> printfloat(a);
0x418a0000
\end{verbatim}

\texttt{Sollya} can parse these memory-dump hexadecimal notation back in any \texttt{display} mode. Remark that the difference of this memory-dump notation with the hexadecimal notation (as defined above) is made by the presence or absence of a $p$ indicator.

### 4 Variables

As already explained, \texttt{Sollya} can manipulate variate functional expressions in one variable. These expressions contain a unique free variable the name of which is fixed by its first usage in an expression
that is not a left-hand-side of an assignment. This global and unique free variable is a variable in the mathematical sense of the term.

Sollya also provides variables in the sense programming languages give to the term. These variables, that must be different in their name from the global free variable, may be global or declared and attached to a block of statements, i.e. a begin-end-block. These programming language variables may hold any object of the Sollya language, as for example functional expressions, strings, intervals, constant values, procedures, external functions and procedures, etc.

Global variables need not to be declared. They start existing, i.e. can be correctly used in expressions that are not left-hand-sides of assignments, when they are assigned a value in an assignment. Since they are global, this kind of variables is recommended only for small Sollya scripts. Larger scripts with code reuse should use declared variables in order to avoid name clashes for example in loop variables.

Declared variables are attached to a begin-end-block. The block structure builds scopes for declared variables. Declared variables in inner scopes shadow variables (global and declared) of outer scopes. The global free variable, i.e. the mathematical variable for variate functional expressions in one variable, cannot be shadowed. Variables are declared using var keyword. See section 8.156 for details on its usage and semantic.

The following code examples illustrate the usage of variables.

```
> f = exp(x);
> f;
exp(x)
> a = "Hello world";
> a;
Hello world
> b = 5;
> f(b);
Warning: rounding has happened. The value displayed is a faithful rounding of the true result.
1.4841315910257660342115580040552279623487667593878e2
> {var b; b = 4; f(b); ;}
Warning: rounding has happened. The value displayed is a faithful rounding of the true result.
5.45981500331442390781102612028608784027907370386137e1
> {var x; x = 3; ;}
Warning: the identifier "x" is already bound to the current free variable.
It cannot be declared as a local variable. The declaration of "x" will have no effect.
Warning: the identifier "x" is already bound to the free variable, to a library function or to an external procedure.
The command will have no effect.
Warning: the last assignment will have no effect.
> {var a, b; a=5; b=3; {var a; var b; b = true; a = 1; a; b;}; a; b; }
1
true
5
3
> a;
Hello world
```

Remark that a variable identifier, just as every identifier in Sollya, contains at least one character, starting with a ASCII letter or one of the special symbols “_”, “$” or “§” and continuing with ASCII letters, special symbols or numerical digits.
5 Data types

Sollya has a (very) basic system of types. If you try to perform an illicit operation (such as adding a number and a string, for instance), you will get a typing error. Let us see the available data types.

5.1 Booleans

There are two special values true and false. Boolean expressions can be constructed using the boolean connectors && (and), || (or), ! (not), and comparisons.

The comparison operators <, <=, > and >= can only be used between two numbers or constant expressions.

The comparison operators == and != are polymorphic. You can use it to compare any two objects, like two strings, two intervals, etc. Note that testing the equality between two functions will return true if and only if the expression trees representing the two functions are exactly the same. See 8.44 for an exception concerning the special object error. Example:

```latex
> 1+x==1+x;
true
```

5.2 Numbers

Sollya represents numbers as binary multi-precision floating-point values. For integer values and values in dyadic, binary, hexadecimal or memory dump notation, it automatically uses a precision needed for representing the value exactly. Additionally, automatic precision adaption takes place for all integer values (even in decimal notation) written without the exponent sign e or with the exponent sign e and an exponent sufficiently small that they are less than 10^{999}. Otherwise the values are represented with the current precision prec. A number in an expression is rounded to the precision prec when the expression gets evaluated:

```latex
> prec=12!;
> 4097.1;
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
4098
> 4097.1+1;
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
4099
```

Note that each variable has its own precision that corresponds to its intrinsic precision or, if it cannot be represented, to the value of prec when the variable was set. Thus you can work with variables having a precision bigger than the current precision.

The same way, if you define a function that refers to some constant, this constant is stored in the function with the current precision and will keep this value in the future, even if prec becomes smaller.

If you define a function that refers to some variable, the precision of the variable is kept, independently of the current precision:
5.3 Intervals

Intervals are composed of two numbers or constant expressions representing the lower and the upper bound. These values are separated either by commas or semi-colons:

> d=[1;2];
> d2=[1,1+1];
> d==d2;
true

If bounds are defined by constant expressions, these are evaluated to floating-point numbers using the current precision. Numbers or variables containing numbers keep their precision for the interval bounds. Interval bound evaluation is performed in a way that ensures the inclusion property: all points in the original, unevaluated interval will be contained in the interval with its bounds evaluated to floating-point numbers. Remark that evaluation bounds defined by constant expressions includes π:

> prec = 300!;
> a = 4097.1;
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 300 bits.
If safe computation is needed, try to increase the precision.
> prec = 12!;
> d = [4097.1; a];
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
> prec = 30!;
> d;
[4.0971e3;4098]
> prec = 30!;
> [-pi;pi];
Warning: the given expression is not a constant but an expression to evaluate.
Warning: the given expression is not a constant but an expression to evaluate.
[-3.141592659;3.141592659]

You can get the upper-bound (respectively the lower-bound) of an interval with the function sup (respectively inf). The middle of the interval is got with the function mid. Note that these functions
can also be used on numbers (in that case, the number is interpreted as an interval containing only one
single point. Thus the functions $\text{inf}$, $\text{mid}$ and $\text{sup}$ are just the identity):

```
> d=[1;3];
> inf(d);
1
> mid(d);
2
> sup(4);
4
```

Remark that the $\text{mid}$ operator never provokes a rounding. It is rewritten as an unevaluated expression
in terms of $\text{inf}$ and $\text{sup}$.

### 5.4 Functions

Sollya knows only functions with one single variable. The first time in a session that an unbound name
is used (without being assigned) it determines the name used to refer to the free variable.

The basic functions available in Sollya are the following:

- $+$, $-$, $\times$, $/$, $^$
- $\text{sqrt}$
- $\text{abs}$
- $\sin$, $\cos$, $\tan$, $\sinh$, $\cosh$, $\tanh$
- $\text{asin}$, $\text{acos}$, $\text{atan}$, $\text{asinh}$, $\text{atanh}$
- $\exp$, $\expm1$ (defined as $\expm1(x) = \exp(x) - 1$)
- $\log$ (natural logarithm), $\log_2$ (binary logarithm), $\log_{10}$ (decimal logarithm), $\log_{1p}$ (defined as
  $\log_{1p}(x) = \log(1 + x)$)
- $\text{erf}$, $\text{erfc}$

The constant $\pi$ is available through the keyword $\text{pi}$ as a 0-ary function: its behavior is exactly the
same as if it were a constant with an infinite precision:

```
> display=binary!;
> prec=12!;
> a=pi;
> a;
Warning: rounding has happened. The value displayed is a faithful rounding of th
e true result.
1.10010010001_2 * 2^(1)
> prec=30!;
> a;
Warning: rounding has happened. The value displayed is a faithful rounding of th
e true result.
1.100100100001111110110101001_2 * 2^(1)
```
5.5 Strings

Anything written between quotes is interpreted as a string. The infix operator @ concatenates two strings. To get the length of a string, use the length function. You can access the i-th character of a string using brackets (see the example below). There is no character type in Sollya: the i-th character of a string is returned as a string itself.

```
> s1 = "Hello "; s2 = "World!";
> s = s1@s2;
> length(s);
12
> s[0];
H
> s[11];
!
```

Strings may contain the following escape sequences: \, \^, \?, \*, \n, \t, \a, \b, \f, \r, \v, \x[hexadecimal number] and \[octal number]. Refer to the C99 standard for their meaning.

5.6 Particular values

Sollya knows some particular values. These values do not really have a type but they can be stored in variables and in lists. A (possibly not exhaustive) list of such values is the following:

- on, off (see sections 8.96 and 8.95)
- dyadic, powers, binary, decimal, hexadecimal (see sections 8.40, 8.107, 8.16, 8.26 and 8.66)
- file, postscript, postscriptfile (see sections 8.54, 8.104 and 8.105)
- RU, RD, RN, RZ (see sections 8.135, 8.121, 8.130 and 8.136)
- absolute, relative (see sections 8.2 and 8.124)
- floating, fixed (see sections 8.57 and 8.56)
- double, doubleextended, doubledouble, tripledouble (see sections 8.37, 8.39, 8.38 and 8.154)
- D, DE, DD, TD (see sections 8.37, 8.39, 8.38 and 8.154)
- perturb (see section 8.99)
- honorcoeffprec (see section 8.67)
- default (see section 8.27)
- error (see section 8.44)
- void (see section 8.158)

5.7 Lists

Objects can be grouped into lists. A list can contain elements with different types. As for strings, you can concatenate two lists with @. The function length gives also the length of a list.

You can prepend an element to a list using .: (in O(1)) and you can append an element to a list using .: (in O(n)). The following example illustrates some features:
Lists can be considered as arrays and elements of lists can be referenced using brackets. Possible indices start at 0. The following example illustrates this point:

```plaintext
> l = ["foo"];  
> l = l:.1;     
> l = "bar".l;  
> l;            
["bar", "foo", 1]
> l[1];         
foo
> l@1;          
["bar", "foo", 1, "bar", "foo", 1]
```

Remind that the complexity for accessing an element of the list using indices is $O(n)$.

Lists may contain ellipses indicated by ..., between elements that are constant and evaluate to integers that are incrementally ordered. Sollya translates such ellipses to the full list upon evaluation. Using ellipses between elements that are not constants is not allowed. This feature is provided for ease of programming; remark that the complexity of expanding such lists is high. For illustration, see the following example:

```plaintext
> l = [1,2,3,4,5];  
> l;             
[1, 2, 3, 4, 5]
> l[3];          
4
```

Lists may be continued to infinity by means of the ... indicator after the last element given. At least one element must explicitly be given. If the last element given is a constant expression that evaluates to an integer, the list is considered as continued to infinity by all integers greater than that last element. If the last element is another object, the list is considered as continued to infinity by re-duplicating this last element. Remark that bracket notation is supported for such end-elliptic lists even for implicitly given elements. However, evaluation complexity is high. Combinations of ellipses inside a list and in its end are possible. The usage of lists described here is best illustrated by the following examples:

```plaintext
> [1,...,5];      
[1, 2, 3, 4, 5]
> [1,...,5];      
[1, 2, 3, 4, 5]
> [-5,...,5];    
[-5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5]
> [3,...,1];     
Warning: at least one of the given expressions or a subexpression is not correctly typed  
or its evaluation has failed because of some error on a side-effect.  
error
> [true,...,false];  
Warning: at least one of the given expressions or a subexpression is not correctly typed  
or its evaluation has failed because of some error on a side-effect.  
error
```

Lists may be continued to infinity by means of the ... indicator after the last element given. At least one element must explicitly be given. If the last element given is a constant expression that evaluates to an integer, the list is considered as continued to infinity by all integers greater than that last element. If the last element is another object, the list is considered as continued to infinity by re-duplicating this last element. Remark that bracket notation is supported for such end-elliptic lists even for implicitly given elements. However, evaluation complexity is high. Combinations of ellipses inside a list and in its end are possible. The usage of lists described here is best illustrated by the following examples:
6 Iterative language elements: assignments, conditional statements and loops

6.1 Blocks

Statements in Sollya can be regrouped in blocks, so-called begin-end-blocks. This can be done using the keywords `begin` and `end` or their shorter variants `{` and `}`. Blocks declared this way are considered as one single statement. As already explained in section 4, using begin-end-blocks also opens the possibility of declaring variables through the keyword `var`.

6.2 Assignments

Sollya has two different assignment operators, = and :=. The assignment operator = assigns its right-hand-object “as is”, i.e. without evaluating functional expressions. For instance, \( i = i + 1 \); will dereference the identifier \( i \) with some content, notate it \( y \), build up the expression (function) \( y + 1 \) and assign this expression back to \( i \). In the example, if \( i \) stood for the value 1000, the statement \( i = i + 1 \); will assign 1000 + 1 – and not 1001 – to \( i \). The assignment operator := evaluates constant functional expressions before assigning them. On other expressions it behaves like =. Still in the example, the statement \( i := i + 1 \); really assigns 1001 to \( i \).

Both Sollya assignment operators support indexing of lists or strings elements using brackets on the left-hand-side of the assignment operator. The indexed element of the list or string gets replaced by the right-hand-side of the assignment operator. When indexing strings this way, that right-hand side must evaluate to a string of length 1. End-elliptic lists are supported with their usual semantic for this kind of assignment. When referencing and assigning a value in the implicit part of the end-elliptic list, the list gets expanded to the corresponding length. The indexing of lists on left-hand sides of assignments is reduced to the first order. Multiple indexing of lists of lists is not supported for complexity reasons.

The following examples well illustrate the behavior of assignment statements:
6.3 Conditional statements

Sollya supports conditional statements expressed with the keywords **if**, **then** and optionally **else**. Remark that only conditional statements are supported not conditional expressions.

The following examples illustrate both syntax and semantic of conditional statements in Sollya. Concerning syntax, remark also that there must not be any semicolon before the **else** keyword.

```plaintext
> a = 3;
> b = 4;
> if (a == b) then print("Hello world");
> b = 3;
> if (a == b) then print("Hello world");
Hello world
> if (a == b) then print("You are telling the truth") else print("Liar");
You are telling the truth
```

6.4 Loops

Sollya supports three kinds of loops. General **while-condition** loops can be expressed using the keywords **while** and **do**. Remark that the condition test is executed always before the loop, there is no **do-until-condition** loop. Consider the following examples for both syntax and semantic:

```plaintext
> autosimplify = off;
Automatic pure tree simplification has been deactivated.
> i = 1000;
> i = i + 1;
> print(i);
1000 + 1
> i := i + 1;
> print(i);
1002
> l = [1,...,5];
> print(l);
[1, 2, 3, 4, 5]
> print(l);
[1, 2, 3, 5, 6]
> l[5] = true;
> l;
[true, 1, 2, 3, 5, 6, true]
> s = "Hello world";
> s;
Hello world
> s[1] = "a";
> s;
Hallo world
> l = [true,1,...,5,9...];
> l;
[true, 1, 2, 3, 4, 5, 9...]
> l[13] = "Hello";
> l;
[true, 1, 2, 3, 4, 5, 9, 10, 11, 12, 13, 14, 15, "Hello"...]
```
> verbosity = 0!
> prec = 30!
> i = 5;
> while (expm1(i) > 0) do { expm1(i); i := i - 1; };
1.474131591e2
5.359815e1
1.908553692e1
6.3890561
1.718281827
> print(i);
0

The second kind of loops are loops on a variable ranging from a numerical start value and an end value. These kinds of loops can be expressed using the keywords for, from, to, do and optionally by. The by statement indicates the width of the steps on the variable from the start value to the end value. Once again, syntax and semantic are best explained with an example:

> for i from 1 to 5 do print ("Hello world",i);
Hello world 1
Hello world 2
Hello world 3
Hello world 4
Hello world 5
> for i from 2 to 1 by -0.5 do print("Hello world",i);
Hello world 2
Hello world 1.5
Hello world 1

The third kind of loops are loops on a variables ranging on values contained in a list. In order to ensure the termination of the loop, that list must not be end-elliptic. The loop is expressed using the keywords for, in and do as in the following examples:

> l = [true, false, 1,...,4, "Hello", exp(x)];
> for i in l do i;
true
false
1
2
3
4
Hello
exp(x)

For both types of for loops, assigning the loop variable is allowed and possible. If the loop terminates, the loop variable will contain the value that made the loop condition fail. Consider the following examples:

> for i from 1 to 5 do { if (i == 3) then i = 4 else i; };
1
2
5
> i;
6
7 Functional language elements: procedures

Sollya has some elements of functional languages. In order to avoid confusion with mathematical functions, the associated programming objects are called *procedures* in Sollya.

Sollya procedures are common objects that can be, for example, assigned to variables or stored in lists. Procedures are declared by the `proc` keyword; see section 8.116 for details. The returned procedure object must then be assigned to a variable and can hence be applied to arguments with common application syntax. The `procedure` keyword provides an abbreviation for declaring and assigning a procedure; see section 8.117 for details.

Sollya procedures can return objects using the `return` keyword at the end of the begin-end-block of the procedure. Section 8.128 gives details on the usage of `return`. Procedures further can take any type of object in argument, in particular also other procedures that are then applied to arguments. Procedures can be declared inside other procedures.

Remark that declaring a procedure does not involve any evaluation or other interpretation of the procedure body. In particular, this means that constants are evaluated to floating-point values inside Sollya when the procedure is applied to actual parameters and the global precision valid at this moment.

Sollya procedures are well illustrated by the following examples:
Sollya also supports external procedures, i.e. procedures written in C (or some other language) and dynamically bound to Sollya identifiers. See §8.52 for details.

8 Commands and functions

8.1 abs

Name: abs

the absolute value.

Description:
• abs is the absolute value function. \( \text{abs}(x) = \begin{cases} x & x > 0 \\ -x & x \leq 0 \end{cases} \).

8.2 absolute

Name: absolute
indicates an absolute error for externalplot

Usage:

```
absolute : absolute|relative
```

Description:

• The use of absolute in the command externalplot indicates that during plotting in externalplot an absolute error is to be considered.

See externalplot for details.

Example 1:

```
> bashexecute("gcc -fPIC -c externalplotexample.c");
> bashexecute("gcc -shared -o externalplotexample externalplotexample.o -lmpfr");
> externalplot("./externalplotexample",absolute,exp(x),[-1/2;1/2],12,perturb);
```

See also: externalplot (8.51), relative (8.124), bashexecute (8.15)

8.3 accurateinfnorm

Name: accurateinfnorm
computes a faithful rounding of the infinite norm of a function

Usage:

```
accurateinfnorm(function,range,constant) : (function, range, constant) → constant
accurateinfnorm(function,range,constant,exclusion range 1,.....exclusion range n) : (function, range, constant, range, ..., range) → constant
```

Parameters:

• function represents the function whose infinite norm is to be computed
• range represents the infinite norm is to be considered on
• constant represents the number of bits in the significant of the result
• exclusion range 1 through exclusion range n represent ranges to be excluded

Description:

• The command accurateinfnorm computes an upper bound to the infinite norm of function function in range. This upper bound is the least floating-point number greater than the value of the infinite norm that lies in the set of dyadic floating point numbers having constant significant mantissa bits. This means the value accurateinfnorm evaluates to is at the time an upper bound and a faithful rounding to constant bits of the infinite norm of function function on range range.

If given, the fourth and further arguments of the command accurateinfnorm, exclusion range 1 through exclusion range n the infinite norm of the function function is not to be considered on.

Example 1:
Example 2:

```matlab
> p = remez(exp(x), 5, [-1;1]);
> midpointmode = on!
> infnorm(p - exp(x), [-1;1]);
0.45205~5/7~e-4
> accurateinfnorm(p - exp(x), [-1;1], 40);
4.5205521043867324948450914234854280948638916015625e-5
```

See also: `infnorm` (8.72), `dirtyinfnorm` (8.33), `checkinfnorm` (8.20), `remez` (8.125), `diam` (8.30)

8.4 acos

Name: **acos**

the arccosine function.

Description:

- **acos** is the inverse of the function **cos**: **acos**(y) is the unique number \( x \in [0; \pi] \) such that \( \cos(x)=y \).

- It is defined only for \( y \in [-1; 1] \).

See also: `cos` (8.24)

8.5 acosh

Name: **acosh**

the arg-hyperbolic cosine function.

Description:

- **acosh** is the inverse of the function **cosh**: **acosh**(y) is the unique number \( x \in [0; +\infty] \) such that \( \cosh(x)=y \).

- It is defined only for \( y \in [0; +\infty] \).

See also: `cosh` (8.25)

8.6 and

Name: **&&**

boolean AND operator

Usage:

```matlab
expr1 && expr2 : (boolean, boolean) → boolean
```

Parameters:

- \( expr1 \) and \( expr2 \) represent boolean expressions

Description:
• && evaluates to the boolean AND of the two boolean expressions expr1 and expr2. && evaluates to true iff both expr1 and expr2 evaluate to true.

Example 1:

```plaintext
> true && false;
false
```

Example 2:

```plaintext
> (1 == exp(0)) && (0 == log(1));
true
```

See also: || (8.97), ! (8.93)

### 8.7 append

Name: .:

add an element at the end of a list.

Usage:

```
L .: x : (list, any type) → list
```

Parameters:

• L is a list (possibly empty).

• x is an object of any type.

Description:

• .: adds the element x at the end of the list L.

• Note that since x may be of any type, it can be in particular a list.

Example 1:

```plaintext
> [2,3,4]:.5;
[2, 3, 4, 5]
```

Example 2:

```plaintext
> [1,2,3]:.[4,5,6];
[1, 2, 3, [4, 5, 6]]
```

Example 3:

```plaintext
> []:.1;
[1]
```

See also: .: (8.110), @ (8.22)
8.8 **approx**

Name: \(\sim\)
floating-point evaluation of a constant expression

Usage:

\[
\sim \text{expression} : \text{function} \rightarrow \text{constant} \\
\sim \text{something} : \text{any type} \rightarrow \text{any type}
\]

Parameters:

- \(\text{expression}\) stands for an expression that is a constant
- \(\text{something}\) stands for some language element that is not a constant expression

Description:

- \(\sim \text{expression}\) evaluates the \(\text{expression}\) that is a constant term to a floating-point constant. The evaluation may involve a rounding. If \(\text{expression}\) is not a constant, the evaluated constant is a faithful rounding of \(\text{expression}\) with \textbf{precision} bits, unless the \(\text{expression}\) is exactly 0 as a result of cancellation. In the latter case, a floating-point approximation of some (unknown) accuracy is returned.

- \(\sim\) does not do anything on all language elements that are not a constant expression. In other words, it behaves like the identity function on any type that is not a constant expression. It can hence be used in any place where one wants to be sure that expressions are simplified using floating-point computations to constants of a known precision, regardless of the type of actual language elements.

- \(\sim \text{error}\) evaluates to error and provokes a warning.

- \(\sim\) is a prefix operator not requiring parentheses. Its precedence is the same as for the unary + and − operators. It cannot be repeatedly used without brackets.

**Example 1:**

```plaintext
> print(exp(5));
exp(5)
> print(~exp(5));
1.48413159102576603421115580040552279623487667593878e2
```

**Example 2:**

```plaintext
> autosimplify = off!;
```

**Example 3:**

```plaintext
> print(~sin(5 * pi));
-4.3878064621853914052425209013193794551397356335691e-12715
```

**Example 4:**

```plaintext
> print(~exp(x));
expx
> print(~"Hello");
Hello
```

**Example 5:**

```plaintext
> print(~exp(x*5*Pi));
exp((pi) * 5 * x)
> print(exp(x* ~(5*Pi)));
exp(x * 1.5707963267948966192313216916397514420985846968757e1)
```
Example 6:

```plaintext
> print(~exp(5)\*x);
1.48413159102576603421115580040552279623487667593878e2 \* x
> print( (~exp(5))\*x);
1.48413159102576603421115580040552279623487667593878e2 \* x
> print(~(exp(5)\*x));
exp(5) \* x
```

See also: `evaluate` (8.45), `prec` (8.108), `error` (8.44)

### 8.9 asciiplot

**Name:** asciiplot

plots a function in a range using ASCII characters

**Usage:**

```plaintext
asciiplot(function, range) : (function, range) → void
```

**Parameters:**

- `function` represents a function to be plotted
- `range` represents a range the function is to be plotted in

**Description:**

- `asciiplot` plots the function `function` in range `range` using ASCII characters. On systems that provide the necessary `TIOCGWINSZ` ioctl, Sollya determines the size of the terminal for the plot size if connected to a terminal. If it is not connected to a terminal or if the test is not possible, the plot is of fixed size `77 \times 25` characters. The function is evaluated on a number of points equal to the number of columns available. Its value is rounded to the next integer in the range of lines available. A letter `x` is written at this place. If zero is in the hull of the image domain of the function, a x-axis is displayed. If zero is in range, an y-axis is displayed. If the function is constant or if the range is reduced to one point, the function is evaluated to a constant and the constant is displayed instead of a plot.

**Example 1:**
Example 2:

```latex
> asciiplot(exp(x),[1;2]);
```

Example 3:
Example 4:

```plaintext
> asciiplot(exp(x),[1;1]);
2.71828182845904523536028747135266249775724709369998
```

See also: plot [8.101]

8.10 asin

Name: asin
the arcsine function.

Description:
- asin is the inverse of the function sin: asin(y) is the unique number \( x \in [-\pi/2; \pi/2] \) such that \( \sin(x)=y \).
- It is defined only for \( y \in [-1;1] \).

See also: sin [8.140]

8.11 asinh

Name: asinh
the arg-hyperbolic sine function.

Description:
- asinh is the inverse of the function sinh: asinh(y) is the unique number \( x \in [-\infty; +\infty] \) such that \( \sinh(x)=y \).
- It is defined for every real number y.

See also: sinh [8.141]

8.12 atan

Name: atan
the arctangent function.

Description:
- atan is the inverse of the function tan: atan(y) is the unique number \( x \in [-\pi/2; +\pi/2] \) such that \( \tan(x)=y \).
- It is defined for every real number y.

See also: tan [8.149]

8.13 atanh

Name: atanh
the hyperbolic arctangent function.

Description:
- atanh is the inverse of the function tanh: atanh(y) is the unique number \( x \in [-\infty; +\infty] \) such that \( \tanh(x)=y \).
- It is defined only for \( y \in [-1;1] \).

See also: tanh [8.150]
8.14 autosimplify

Name: autosimplify
activates, deactivates or inspects the value of the automatic simplification state variable

Usage:

\[
\text{autosimplify} = \text{activation value} : \text{on|off} \rightarrow \text{void} \\
\text{autosimplify} = \text{activation value} ! : \text{on|off} \rightarrow \text{void}
\]

Parameters:

- \text{activation value} represents \text{on} or \text{off}, i.e. activation or deactivation

Description:

- An assignment \text{autosimplify} = \text{activation value}, where \text{activation value} is one of \text{on} or \text{off}, activates respectively deactivates the automatic safe simplification of expressions of functions generated by the evaluation of commands or in argument of other commands.

\text{Sollya} commands like \text{remez}, \text{taylor} or \text{rationalapprox} sometimes produce expressions that can be simplified. Constant subexpressions can be evaluated to dyadic floating-point numbers, monomials with coefficients 0 can be eliminated. Further, expressions indicated by the user perform better in many commands when simplified before being passed in argument to a command. When the automatic simplification of expressions is activated, \text{Sollya} automatically performs a safe (not value changing) simplification process on such expression.

The automatic generation of subexpressions can be annoying, in particular if it takes too much time for not enough usage. Further the user might want to inspect the structure of the expression tree returned by a command. In this case, the automatic simplification should be deactivated.

If the assignment \text{autosimplify} = \text{activation value} is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

Example 1:

```
> autosimplify = on !;
> print(x - x);
0
> autosimplify = off ;
Automatic pure tree simplification has been deactivated.
> print(x - x);
x - x
```

Example 2:

```
> autosimplify = on !;
> print(rationalapprox(sin(pi/5.9),7));
0.5
> autosimplify = off !;
> print(rationalapprox(sin(pi/5.9),7));
1 / 2
```

See also: \text{print} (8.111), \text{prec} (8.108), \text{points} (8.103), \text{diam} (8.30), \text{display} (8.35), \text{verbosity} (8.157), \text{canonical} (8.18), \text{taylorrecursions} (8.152), \text{timing} (8.153), \text{fullparentheses} (8.60), \text{midpointmode} (8.88), \text{hopitalrecursions} (8.68), \text{remez} (8.125), \text{rationalapprox} (8.120), \text{taylor} (8.151)
8.15 bashexecute

Name: bashexecute
executes a shell command.

Usage:

bashexecute(command) : string → void

Parameters:

- command is a command to be interpreted by the shell.

Description:

- bashexecute(command) lets the shell interpret command. It is useful to execute some external code within Sollya.
- bashexecute does not return anything. It just executes its argument. However, if command produces an output in a file, this result can be imported in Sollya with help of commands like execute, readFile and parse.

Example 1:

```
> bashexecute("ls /");
bin
boot
cdrom
dev
dev
emul
elem
ehome
initrd
initrd.img
lib
lib32
lib64
lost+found
media
mnt
opt
proc
root
sbin
srv
sys
tmp
usr
var
vmlinuz
```

See also: execute [8.46], readFile [8.122], parse [8.98]

8.16 binary

Name: hexadecimal
special value for global state display

Description:
**hexadecimal** is a special value used for the global state display. If the global state display is equal to hexadecimal, all data will be output in binary notation.

As any value it can be affected to a variable and stored in lists.

See also: decimal (8.26), dyadic (8.40), powers (8.107), hexadecimal (8.66)

### 8.17 boolean

Name: **boolean**

Keyword representing a boolean type

Usage:

```latex
boolean : type type
```

Description:

- **boolean** represents the boolean type for declarations of external procedures by means of externalproc.

Remark that in contrast to other indicators, type indicators like **boolean** cannot be handled outside the externalproc context. In particular, they cannot be assigned to variables.

See also: externalproc (8.52), constant (8.23), function (8.61), integer (8.73), list of (8.80), range (8.119), string (8.144)

### 8.18 canonical

Name: **canonical**

Brings all polynomial subexpressions of an expression to canonical form or activates, deactivates or checks canonical form printing

Usage:

```latex
canonical(function) : function → function
canonical = activation value : on|off → void
canonical = activation value ! : on|off → void
```

Parameters:

- **function** represents the expression to be rewritten in canonical form
- **activation value** represents on or off, i.e. activation or deactivation

Description:

- The command **canonical** rewrites the expression representing the function **function** in a way such that all polynomial subexpressions (or the whole expression itself, if it is a polynomial) are written in canonical form, i.e. as a sum of monomials in the canonical base. The canonical base is the base of the integer powers of the global free variable. The command **canonical** does not endanger the safety of computations even in Sollya's floating-point environment: the function returned is mathematically equal to the function **function**.

- An assignment **canonical = activation value**, where **activation value** is one of on or off, activates respectively deactivates the automatic printing of polynomial expressions in canonical form, i.e. as a sum of monomials in the canonical base. If automatic printing in canonical form is deactivated, automatic printing yields to displaying polynomial subexpressions in Horner form.

If the assignment **canonical = activation value** is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.
Example 1:

```plaintext
> print(canonical(1 + x * (x + 3 * x^2)));
1 + x^2 + 3 * x^3
> print(canonical((x + 1)^7));
1 + 7 * x + 21 * x^2 + 35 * x^3 + 35 * x^4 + 21 * x^5 + 7 * x^6 + x^7
```

Example 2:

```plaintext
> print(canonical(exp((x + 1)^5) - log(asin(((x + 2) + x)^4 * (x + 1)) + x)));
exp(1 + 5 * x + 10 * x^2 + 10 * x^3 + 5 * x^4 + x^5) - log(asin(16 + 80 * x + 16
0 * x^2 + 160 * x^3 + 80 * x^4 + 16 * x^5) + x)
```

Example 3:

```plaintext
> canonical;
off
> (x + 2)^9;
512 + x * (2304 + x * (4608 + x * (5376 + x * (4032 + x * (2016 + x * (672 + x * (144 + x * (18 + x))))))))
> canonical = on;
Canonical automatic printing output has been activated.
> (x + 2)^9;
512 + 2304 * x + 4608 * x^2 + 5376 * x^3 + 4032 * x^4 + 2016 * x^5 + 672 * x^6 +

> (x + 2)^9;
512 + x * (2304 + x * (4608 + x * (5376 + x * (4032 + x * (2016 + x * (672 + x * (144 + x * (18 + x))))))))
```

See also: horner (8.69), print (8.111)

8.19 ceil

Name: ceil

the usual function ceil.

Description:

- ceil is defined as usual: ceil(x) is the smallest integer y such that y ≥ x.
- It is defined for every real number x.

See also: floor (8.58)

8.20 checkinfnorm

Name: checkinfnorm

checks whether the infinite norm of a function is bounded by a value

Usage:

```plaintext
checkinfnorm(function,range,constant) : (function, range, constant) → boolean
```

Parameters:

- function represents the function whose infinite norm is to be checked
range represents the infinite norm is to be considered on

constant represents the upper bound the infinite norm is to be checked to

Description:

- The command `checkinfnorm` checks whether the infinite norm of the given function `function` in the range `range` can be proven (by Sollya) to be less than the given bound `bound`. This means, if `checkinfnorm` evaluates to `true`, the infinite norm has been proven (by Sollya's interval arithmetic) to be less than the bound. If `checkinfnorm` evaluates to `false`, there are two possibilities: either the bound is less than or equal to the infinite norm of the function or the bound is greater than the infinite norm but Sollya could not conclude using its internal interval arithmetic.

`checkinfnorm` is sensitive to the global variable `diam`. The smaller `diam`, the more time Sollya will spend on the evaluation of `checkinfnorm` in order to prove the bound before returning `false` although the infinite is bounded by the bound. If `diam` is equal to 0, Sollya will eventually spend infinite time on instances where the given bound `bound` is less or equal to the infinite norm of the function `function` in range `range`. In contrast, with `diam` being zero, `checkinfnorm` evaluates to `true` iff the infinite norm of the function in the range is bounded by the given bound.

Example 1:

```plaintext
> checkinfnorm(sin(x), [0;1.75], 1);
true
> checkinfnorm(sin(x), [0;1.75], 1/2); checkinfnorm(sin(x), [0;20/39], false
> 1/2);
true
```

Example 2:

```plaintext
> p = remez(exp(x), 5, [-1;1]);
> b = dirtyinfnorm(p - exp(x), [-1;1]);
> checkinfnorm(p - exp(x), [-1;1], b);
false
> b1 = round(b, 15, RU);
> checkinfnorm(p - exp(x), [-1;1], b1);
true
> b2 = round(b, 25, RU);
> checkinfnorm(p - exp(x), [-1;1], b2);
false
> diam = 1b-20!;
> checkinfnorm(p - exp(x), [-1;1], b2);
true
```

### 8.21 coeff

Name: `coeff`  

gives the coefficient of degree n of a polynomial

Usage:

```
coeff(f, n) : (function, integer) → constant
```

Parameters:

- f is a function (usually a polynomial).
• $n$ is an integer

Description:
• If $f$ is a polynomial, $\text{coeff}(f, n)$ returns the coefficient of degree $n$ in $f$.
• If $f$ is a function that is not a polynomial, $\text{coeff}(f, n)$ returns 0.

Example 1:

```plaintext
> coeff((1+x)^5,3);
10
```

Example 2:

```plaintext
> coeff(sin(x),0);
0
```

See also: degree [8.28]

### 8.22 concat

Name: @
concatenates two lists or strings.

Usage:

$L1@L2 : (\text{list}, \text{list}) \rightarrow \text{list}$

$string1@string2 : (\text{string}, \text{string}) \rightarrow \text{string}$

Parameters:
• $L1$ and $L2$ are two lists.
• $string1$ and $string2$ are two strings.

Description:
• @ concatenates two lists or strings.

Example 1:

```plaintext
> [1,...,3]@[7,8,9];
[1, 2, 3, 7, 8, 9]
```

Example 2:

```plaintext
> "Hello "@"World!";
Hello World!
```

See also: :: [8.110], :: [8.7]

### 8.23 constant

Name: constant
keyword representing a constant type

Usage:

constant : type type

Description:
**constant** represents the constant type for declarations of external procedures by means of externalproc.

Remark that in contrast to other indicators, type indicators like **constant** cannot be handled outside the externalproc context. In particular, they cannot be assigned to variables.

See also: externalproc (8.52), boolean (8.17), function (8.61), integer (8.73), list of (8.80), range (8.119), string (8.144)

### 8.24 cos

**Name:** cos

the cosine function.

**Description:**

- **cos** is the usual cosine function.
- It is defined for every real number x.

See also: acos (8.4), sin (8.140), tan (8.149)

### 8.25 cosh

**Name:** cosh

the hyperbolic cosine function.

**Description:**

- **cosh** is the usual hyperbolic function: \( \cosh(x) = \frac{e^x + e^{-x}}{2} \).
- It is defined for every real number x.

See also: acosh (8.5), sinh (8.141), tanh (8.150), exp (8.47)

### 8.26 decimal

**Name:** decimal

special value for global state **display**

**Description:**

- **decimal** is a special value used for the global state **display**. If the global state **display** is equal to **decimal**, all data will be output in decimal notation.
  - As any value it can be affected to a variable and stored in lists.

See also: dyadic (8.40), powers (8.107), hexadecimal (8.66), binary (8.16)

### 8.27 default

**Name:** default

default value for some commands.

**Description:**

- **default** is a special value and is replaced by something depending on the context where it is used.
  - It can often be used as a joker, when you want to specify one of the optional parameters of a command and not the others: set the value of uninteresting parameters to **default**.
  - Global variables can be reset by affecting them the special value **default**.
Example 1:

```plaintext
> p = remez(exp(x),5,[0;1],default,1e-5);
> q = remez(exp(x),5,[0;1],1,1e-5);
> p==q;
true
```

Example 2:

```plaintext
> prec;
165
> prec=200;
The precision has been set to 200 bits.
> prec=default;
The precision has been set to 165 bits.
```

8.28 degree

Name: degree
gives the degree of a polynomial.

Usage:

```
degree(f) : function → integer
```

Parameters:

- $f$ is a function (usually a polynomial).

Description:

- If $f$ is a polynomial, $\text{degree}(f)$ returns the degree of $f$.
- Contrary to the usage, Sollya considers that the degree of the null polynomial is 0.
- If $f$ is a function that is not a polynomial, $\text{degree}(f)$ returns -1.

Example 1:

```plaintext
> degree((1+x)*(2+5*x^2));
3
> degree(0);
0
```

Example 2:

```plaintext
> degree(sin(x));
-1
```

See also: coeff [8.21]

8.29 denominator

Name: denominator
gives the denominator of an expression

Usage:

```
denominator(expr) : function → function
```

Parameters:
• \textit{expr} represents an expression

Description:

• If \textit{expr} represents a fraction \textit{expr1/expr2}, \textbf{denominator}(\textit{expr}) returns the denominator of this fraction, i.e. \textit{expr2}.

  If \textit{expr} represents something else, \textbf{denominator}(\textit{expr}) returns 1.

  Note that for all expressions \textit{expr}, \textbf{numerator}(\textit{expr}) / \textbf{denominator}(\textit{expr}) is equal to \textit{expr}.

Example 1:

\begin{verbatim}
> denominator(5/3);
3
\end{verbatim}

Example 2:

\begin{verbatim}
> denominator(exp(x));
1
\end{verbatim}

Example 3:

\begin{verbatim}
> a = 5/3;
> b = numerator(a)/denominator(a);
> print(a);
5 / 3
> print(b);
5 / 3
\end{verbatim}

Example 4:

\begin{verbatim}
> a = exp(x/3);
> b = numerator(a)/denominator(a);
> print(a);
exp(x / 3)
> print(b);
exp(x / 3)
\end{verbatim}

See also: \textbf{numerator} \textit{8.94}

\textbf{8.30 diam}

Name: \textbf{diam}

parameter used in safe algorithms of \textit{Sollya} and controlling the maximal length of the involved intervals.

Description:

• \textbf{diam} is a global variable. Its value represents the maximal length allowed for intervals involved in safe algorithms of \textit{Sollya} (namely \textit{infnorm}, \textit{checkinfnorm}, \textit{accurateinfnorm}, \textit{integral}, \textit{findzeros}).

• More precisely, \textbf{diam} is relative to the diameter of the input interval of the command. For instance, suppose that \textbf{diam}=1e-5: if \textit{infnorm} is called on interval [0, 1], the maximal length of an interval will be 1e-5. But if it is called on interval [0, 1e−3], the maximal length will be 1e-8.

See also: \textbf{infnorm} \textit{8.72}, \textbf{checkinfnorm} \textit{8.20}, \textbf{accurateinfnorm} \textit{8.3}, \textbf{integral} \textit{8.74}, \textbf{findzeros} \textit{8.55}

36
**8.31 diff**

Name: **diff**
differentiation operator

Usage:

```
diff(function) : function → function
```

Parameters:
- *function* represents a function

Description:
- **diff(function)** returns the symbolic derivative of the function *function* by the global free variable.
  - If *function* represents a function symbol that is externally bound to some code by **library**, the derivative is performed as a symbolic annotation to the returned expression tree.

Example 1:

```
> diff(sin(x));
cos(x)
```

Example 2:

```
> diff(x);
1
```

Example 3:

```
> diff(x^x);
x^x * (1 + log(x))
```

See also: **library** [8.79]

**8.32 dirtyfindzeros**

Name: **dirtyfindzeros**
gives a list of numerical values listing the zeros of a function on an interval.

Usage:

```
dirtyfindzeros(f, I) : (function, range) → list
```

Parameters:
- *f* is a function.
- *I* is an interval.

Description:
- **dirtyfindzeros(f, I)** returns a list containing some zeros of *f* in the interval *I*. The values in the list are numerical approximation of the exact zeros. The precision of these approximations is approximately the precision stored in **prec**. If *f* does not have two zeros very close to each other, it can be expected that all zeros are listed. However, some zeros may be forgotten. This command should be considered as a numerical algorithm and should not be used if safety is critical.
  - More precisely, the algorithm relies on global variables **prec** and **points** and is the following: let *n* be the value of variable **points** and *t* be the value of variable **prec**.
– Evaluate $|f|$ at $n$ evenly distributed points in the interval $I$. the precision used is automatically chosen in order to ensure that the sign is correct.

– Whenever $f$ changes its sign for two consecutive points, find an approximation $x$ of its zero with precision $t$ using Newton’s algorithm. The number of steps in Newton’s iteration depends on $t$: the precision of the approximation is supposed to be doubled at each step.

– Add this value to the list.

Example 1:

```matlab
> dirtyfindzeros(sin(x),[-5;5]);
[|-3.14159265358979323846264338327950288419716939937508, 0, 3.14159265358979323846264338327950288419716939937508|]
```

Example 2:

```matlab
> L1=dirtyfindzeros(x^2*sin(1/x),[0;1]);
> points=1000;
> L2=dirtyfindzeros(x^2*sin(1/x),[0;1]);
> length(L1); length(L2);
18
25
```

See also: `prec` [8.108], `points` [8.103], `findzeros` [8.55]

### 8.33 dirtyinfnorm

Name: `dirtyinfnorm` computes a numerical approximation of the infinite norm of a function on an interval.

Usage:

```
dirtyinfnorm(f,I) : (function, range) → constant
```

Parameters:

- $f$ is a function.
- $I$ is an interval.

Description:

- `dirtyinfnorm(f,I)` computes an approximation of the infinite norm of the given function $f$ on the interval $I$, e.g. $\max_{x \in I} |f(x)|$.

- The interval must be bound. If the interval contains one of -Inf or +Inf, the result of `dirtyinfnorm` is NaN.

- The result of this command depends on the global variables `prec` and `points`. Therefore, the returned result is generally a good approximation of the exact infinite norm, with precision `prec`. However, the result is generally underestimated and should not be used when safety is critical. Use `infnorm` instead.

- The following algorithm is used: let $n$ be the value of variable `points` and $t$ be the value of variable `prec`.
  
  – Evaluate $|f|$ at $n$ evenly distributed points in the interval $I$. The evaluation are faithful roundings of the exact results at precision $t$.
  
  – Whenever the derivative of $f$ changes its sign for two consecutive points, find an approximation $x$ of its zero with precision $t$. Then compute a faithful rounding of $|f(x)|$ at precision $t$.  

38
Return the maximum of all computed values.

Example 1:

```plaintext
> dirtyinfnorm(sin(x),[-10;10]);
1
```

Example 2:

```plaintext
> prec=15!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.45856
> prec=40!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.45852857135
> prec=100!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.45852857136438147455024
> prec=200!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.4585285713623764438147455023841718299214087993682374094153
```

Example 3:

```plaintext
> dirtyinfnorm(x^2, [log(0);log(1)]);
@NaN@
```

8.34 dirtyintegral

Name: **dirtyintegral**

computes a numerical approximation of the integral of a function on an interval.

Usage:

```plaintext
dirtyintegral(f,I) : (function, range) → constant
```

Parameters:

- `f` is a function.
- `I` is an interval.

Description:

- **dirtyintegral**\((f,I)\) computes an approximation of the integral of \(f\) on \(I\).
- The interval must be bound. If the interval contains one of -Inf or +Inf, the result of **dirtyintegral** is NaN, even if the integral has a meaning.
- The result of this command depends on the global variables `prec` and `points`. The method used is the trapezium rule applied at \(n\) evenly distributed points in the interval, where \(n\) is the value of global variable `points`.
- This command computes a numerical approximation of the exact value of the integral. It should not be used if safety is critical. In this case, use command **integral** instead.
- Warning: this command is known to be currently unsatisfactory. If you really need to compute integrals, think of using an other tool or report a feature request to sylvain.chevillard@ens-lyon.fr.
Example 1:

```plaintext
> sin(10);
-0.5440211108893698134047466185137728168364301291621
> dirtyintegral(cos(x),[0;10]);
-0.54403049065152629822448058882475382036536298356281
> points=2000!;
> dirtyintegral(cos(x),[0;10]);
-0.544019975115832197222697312583199035995837926892
```

See also: `prec [8.108]`, `points [8.103]`, `integral [8.74]`

### 8.35 display

**Name:** display

sets or inspects the global variable specifying number notation

**Usage:**

```plaintext
display = notation value : decimal|binary|dyadic|powers|hexadecimal → void
display = notation value ! : decimal|binary|dyadic|powers|hexadecimal → void
```

**Parameters:**

- `notation value` represents a variable of type `decimal|binary|dyadic|powers|hexadecimal`

**Description:**

- An assignment `display = notation value`, where `notation value` is one of `decimal`, `dyadic`, `powers`, `binary` or `hexadecimal`, activates the corresponding notation for output of values in `print`, `write` or at the Sollya prompt.

If the global notation variable `display` is `decimal`, all numbers will be output in scientific decimal notation. If the global notation variable `display` is `dyadic`, all numbers will be output as dyadic numbers with Gappa notation. If the global notation variable `display` is `powers`, all numbers will be output as dyadic numbers with a notation compatible with Maple and PARI/GP. If the global notation variable `display` is `binary`, all numbers will be output in binary notation. If the global notation variable `display` is `hexadecimal`, all numbers will be output in C99/ IEEE754R notation. All output notations can be parsed back by Sollya, inducing no error if the input and output precisions are the same (see `prec`).

If the assignment `display = notation value` is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

**Example 1:**
8.36 divide

Name: /  
division function

Usage:

\[ function1 \div function2 : (\text{function, function}) \to \text{function} \]

Parameters:

- \( function1 \) and \( function2 \) represent functions

Description:

- \( \div \) represents the division (function) on reals. The expression \( function1 \div function2 \) stands for the function composed of the division function and the two functions \( function1 \) and \( function2 \), where \( function1 \) is the numerator and \( function2 \) the denominator.

Example 1:

\begin{verbatim}
> 5 / 2;
2.5
\end{verbatim}

Example 2:

\begin{verbatim}
> x / 2;
x * 0.5
\end{verbatim}

Example 3:

\begin{verbatim}
> x / x;
1
\end{verbatim}
Example 4:

```
> 3 / 0;
@Inf@
```

Example 5:

```
> diff(sin(x) / exp(x));
(exp(x) * cos(x) - sin(x) * exp(x)) / exp(x)^2
```

See also: + (8.102), - (8.89), * (8.90), ^ (8.106)

8.37 double

Names: double, D

Rounding to the nearest IEEE double.

Description:

- **double** is both a function and a constant.

- As a function, it rounds its argument to the nearest double precision number. Subnormal numbers are supported as well as standard numbers: it is the real rounding described in the standard.

- As a constant, it symbolizes the double precision format. It is used in contexts when a precision format is necessary, e.g. in the commands `roundcoefficients` and `implementpoly`. See the corresponding help pages for examples.

Example 1:

```
> display=binary!;
> D(0.1);
1.100110011001100110011001100110011001100110011001101_2 * 2^(-4)
> D(4.17);
1.000010101110000101000111101011100001010001111010111_2 * 2^(2)
> D(1.011_2 * 2^(-1073));
1.1_2 * 2^(-1073)
```

See also: `doubleextended` (8.30), `doubledouble` (8.38), `tripledouble` (8.154), `roundcoefficients` (8.132), `implementpoly` (8.70)

8.38 doubledouble

Names: doubledouble, DD

Represents a number as the sum of two IEEE doubles.

Description:

- **doubledouble** is both a function and a constant.

- As a function, it rounds its argument to the nearest number that can be written as the sum of two double precision numbers.

- The algorithm used to compute `doubledouble(x)` is the following: let $x_h = \text{double}(x)$ and let $x_l = \text{double}(x-x_h)$. Return the number $x_h+x_l$. Note that if the current precision is not sufficient to represent exactly $x_h+x_l$, a rounding will occur and the result of `doubledouble(x)` will be useless.

- As a constant, it symbolizes the double-double precision format. It is used in contexts when a precision format is necessary, e.g. in the commands `roundcoefficients` and `implementpoly`. See the corresponding help pages for examples.
Example 1:

```plaintext
> verbosity=1;
> a = 1 + 2^(-100);
> DD(a);
Warning: rounding a value computed on less than 106 bits to double-double precision.
1.000000000000000000000000000000788860952210118054
> prec=50!;
> DD(a);
Warning: rounding a value computed on less than 106 bits to double-double precision.
Warning: double rounding occurred on invoking the double-double rounding operator.
Try to increase the working precision.
1
```

See also: double [8.37], doubleextended [8.39], triplicatedouble [8.154], roundcoefficients [8.132], implementpoly [8.70]

### 8.39 doubleextended

Names: doubleextended, DE

dcomputes the nearest number with 64 bits of mantissa.

Description:

- **doubleextended** is a function that computes the nearest floating-point number with 64 bits of mantissa to a given number. Since it is a function, it can be composed with other functions of Sollya such as exp, sin, etc.

- It does not handle subnormal numbers. The range of possible exponents is the range used for all numbers represented in Sollya (e.g. basically the range used in the library MPFR).

- Since it is a function and not a command, its behavior is a bit different from the behavior of round(x,64,RN) even if the result is exactly the same. round(x,64,RN) is immediately evaluated whereas doubleextended(x) can be composed with other functions (and thus be plotted and so on).

- Be aware that doubleextended cannot be used as a constant to represent a format in the commands roundcoefficients and implementpoly (contrary to D, DD, and TD).

Example 1:

```plaintext
> display=binary!;
> DE(0.1);
1.100110011001100110011001100110011001100110011001100110011001101_2 * 2^(-4)
> round(0.1,64,RN);
1.100110011001100110011001100110011001100110011001100110011001101_2 * 2^(-4)
```

Example 2:

```plaintext
> D(2^(-2000));
0
> DE(2^(-2000));
8.7098098162172166755761954947788722958591037427053e-603
```

Example 3:
> verbosity=1;
> f = sin(DE(x));
> f(pi);
Warning: rounding has happened. The value displayed is a faithful rounding of the true result.
-5.0165576126683320235573270803307570138315616702549e-20
> g = sin(round(x,64,RN));
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.

See also: double [8.37], doubledouble [8.38], tripledouble [8.154], round [8.131]

8.40 dyadic

Name: dyadic
special value for global state display

Description:

- **dyadic** is a special value used for the global state display. If the global state display is equal to dyadic, all data will be output in dyadic notation with numbers displayed in Gappa format.

As any value it can be affected to a variable and stored in lists.

See also: decimal [8.26], powers [8.107], hexadecimal [8.66], binary [8.16]

8.41 equal

Name: ==
equality test operator

Usage:

```
expr1 == expr2 : (any type, any type) → boolean
```

Parameters:

- **expr1** and **expr2** represent expressions

Description:

- The operator == evaluates to true iff its operands **expr1** and **expr2** are syntactically equal and different from error or constant expressions that are not constants and that evaluate to the same floating-point number with the global precision prec. The user should be aware of the fact that because of floating-point evaluation, the operator == is not exactly the same as the mathematical equality.

Example 1:

> "Hello" == "Hello";
true
> "Hello" == "Salut";
false
> "Hello" == 5;
false
> 5 + x == 5 + x;
true

Example 2:
Example 3:

\[
\begin{align*}
&> \sin (\pi / 6) = 1 / 2 \times \sqrt{3}; \\
&\text{false}
\end{align*}
\]

Example 4:

\[
\begin{align*}
&> \text{prec} = 12; \\
&\text{The precision has been set to 12 bits.} \\
&> 16384.1 = 16385.1; \\
&\text{true}
\end{align*}
\]

Example 5:

\[
\begin{align*}
&> \text{error} = \text{error}; \\
&\text{false}
\end{align*}
\]

See also: \(!= (8.91), > (8.63), >= (8.62), <= (8.77), < (8.85), ! (8.93), && (8.6), || (8.97), error (8.44), prec (8.108)\]

8.42 erf

Name: erf
the error function.

Description:

- \(\text{erf} \) is the error function defined by:
  \[
  \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.
  \]
  - It is defined for every real number \(x\).

See also: erfc (8.43), exp (8.47)

8.43 erfc

Name: erfc
the complementary error function.

Description:

- \(\text{erfc} \) is the complementary error function defined by \(\text{erfc}(x) = 1 - \text{erf}(x)\).
  - It is defined for every real number \(x\).

See also: erf (8.42)
8.44  error

Name: error
expression representing an input that is wrongly typed or that cannot be executed

Usage:

```plaintext
error : error
```

Description:

- The variable `error` represents an input during the evaluation of which a type or execution error has been detected or is to be detected. Inputs that are syntactically correct but wrongly typed evaluate to `error` at some stage. Inputs that are correctly typed but containing commands that depend on side-effects that cannot be performed or inputs that are wrongly typed at meta-level (cf. `parse`), evaluate to `error`.

Remark that in contrast to all other elements of the Sollya language, `error` compares neither equal nor unequal to itself. This provides a means of detecting syntax errors inside the Sollya language itself without introducing issues of two different wrongly typed input being equal.

Example 1:

```plaintext
> print(5 + "foo");
error
```

Example 2:

```plaintext
> error;
error
```

Example 3:

```plaintext
> error == error;
false
> error != error;
false
```

Example 4:

```plaintext
> correct = 5 + 6;
> incorrect = 5 + "foo";
> (correct == error || correct != error);
true
> (incorrect == error || incorrect != error);
false
```

See also: void [8.158], `parse` [8.98]

8.45  evaluate

Name: evaluate
evaluates a function at a constant point or in a range

Usage:

```plaintext
evaluate(function, constant) : (function, constant) → constant | range
evaluate(function, range) : (function, range) → range
evaluate(function, function2) : (function, function) → function
```
Parameters:

- *function* represents a function
- *constant* represents a constant point
- *range* represents a range
- *function2* represents a function that is not constant

Description:

- If its second argument is a constant *constant*, **evaluate** evaluates its first argument *function* at the point indicated by *constant*. This evaluation is performed in a way that the result is a faithful rounding of the real value of the *function* at *constant* to the current global precision. If such a faithful rounding is not possible, **evaluate** returns a range surely encompassing the real value of the *function* at *constant*. If even interval evaluation is not possible because the expression is undefined or numerically unstable, NaN will be produced.

- If its second argument is a range *range*, **evaluate** evaluates its first argument *function* by interval evaluation on this range *range*. This ensures that the image domain of the function *function* on the preimage domain *range* is surely enclosed in the returned range.

- If its second argument is a function *function2* that is not a constant, **evaluate** replaces all occurrences of the free variable in function *function* by function *function2*.

Example 1:

```plaintext
> print(evaluate(sin(pi * x), 2.25));
0.70710678118654752440084436210484903928483593768847
```

Example 2:

```plaintext
> print(evaluate(sin(pi * x), 2));
[-1.729864525143812695165058615031098129542836767991679e-12715;7.5941198201187963145069564314525661706039084390067e-12716]
```

Example 3:

```plaintext
> print(evaluate(sin(pi * x), [2, 2.25]));
[-5.143390272677254630046998919961912407349224165421e-50;0.70710678118654752440084436210484903928483593768847]
```

Example 4:

```plaintext
> print(evaluate(sin(pi * x), 2 + 0.25 * x));
sin((pi) * (2 + 0.25 * x))
```

Example 5:

```plaintext
> print(evaluate(sin(pi * 1/x), 0));
[@NaN@;@NaN@]
```

See also: **isevaluable** [8.76]
8.46 execute

Name: execute
executes the content of a file

Usage:

execute(filename) : string → void

Parameters:

- filename is a string representing a file name

Description:

- execute opens the file indicated by filename, and executes the sequence of commands it contains. This command is evaluated at execution time: this way you can modify the file filename (for instance using bashexecute) and execute it just after.

- If filename contains a command execute, it will be executed recursively.

- If filename contains a call to restart, it will be neglected.

- If filename contains a call to quit, the commands following quit in filename will be neglected.

Example 1:

```
> a=2;
> a;
2
> print("a=1;") > "example.sollya";
> execute("example.sollya");
> a;
1
```

Example 2:

```
> verbosity=1!
> print("a=1; restart; a=2;") > "example.sollya";
> execute("example.sollya");
Warning: a restart command has been used in a file read into another. This restart command will be neglected.
> a;
2
```

Example 3:

```
> verbosity=1!
> print("a=1; quit; a=2;") > "example.sollya";
> execute("example.sollya");
Warning: the execution of a file read by execute demanded stopping the interpretation but it is not stopped.
> a;
1
```

See also: parse (8.98), readfile (8.122), write (8.160), print (8.111), bashexecute (8.15)
8.47 exp

Name: exp
the exponential function.

Description:

- exp is the usual exponential function defined as the solution of the ordinary differential equation
  \( y' = y \) with \( y(0) = 1 \).
- exp(x) is defined for every real number x.

See also: exp (8.47), log (8.81)

8.48 expand

Name: expand
expands polynomial subexpressions

Usage:

\[ \text{expand(function)} : \text{function} \rightarrow \text{function} \]

Parameters:

- function represents a function

Description:

- expand(function) expands all polynomial subexpressions in function function as far as possible. Factors of sums are multiplied out, power operators with constant positive integer exponents are replaced by multiplications and divisions are multiplied out, i.e. denominators are brought at the most interior point of expressions.

Example 1:

\[ > \text{print(expand(x^3));} \]
\[ x * x * x \]

Example 2:

\[ > \text{print(expand((x + 2)^3 + 2 * x));} \]
\[ 8 + 12 * x + 6 * x * x + x * x * x + 2 * x \]

Example 3:

\[ > \text{print(expand(exp((x + (x + 3))^5));} \]
\[ \text{exp(243 + 405 * x + 270 * x * x + 90 * x * x * x + 15 * x * x * x * x * x + x + 10 + 9 * x * x * x} \\
\[ x * x * x + x * x + x * x + 10 + x * x * x * 90 + 6 * x * x * x * x * 10 + x} \\
\[ * x * x * x * x * 10 + x * x * x * x * x * 5 + x + 15 * x * x * x * x + x * x * x * x} \\
\[ x * x) \]

See also: simplify (8.138), simplifysafe (8.139), horner (8.69)
8.49 expm1

Name: expm1
translated exponential function.

Description:

- expm1 is defined by expm1(x) = \exp(x) - 1.
- It is defined for every real number x.

See also: \exp (8.47)

8.50 exponent

Name: exponent
returns the scaled binary exponent of a number.

Usage:

\[
\text{exponent}(x) : \text{constant} \rightarrow \text{integer}
\]

Parameters:

- \(x\) is a dyadic number.

Description:

- exponent(x) is by definition 0 if \(x\) equals 0, NaN, or Inf.
- If \(x\) is not zero, it can be uniquely written as \(x = m \cdot 2^e\) where \(m\) is an odd integer and \(e\) is an integer. \text{exponent}(x) returns \(e\).

Example 1:

\[
\begin{align*}
> & \text{a}=\text{round}(\pi, 20, \text{RN}); \\
> & \text{e}=\text{exponent}(\text{a}); \\
> & \text{e}; \\
> & -17 \\
> & \text{m}=\text{mantissa}(\text{a}); \\
> & \text{a}=\text{m} \cdot 2^\text{e}; \\
> & 0
\end{align*}
\]

See also: mantissa [8.86], precision [8.109]

8.51 externalplot

Name: externalplot
plots the error of an external code with regard to a function

Usage:

\[
\text{externalplot}(\text{filename}, \text{mode}, \text{function}, \text{range}, \text{precision}) : (\text{string}, \text{absolute|relative}, \text{function}, \text{range}, \text{integer}) \rightarrow \text{void}
\]
\[
\text{externalplot}(\text{filename}, \text{mode}, \text{function}, \text{range}, \text{precision}, \text{perturb}) : (\text{string}, \text{absolute|relative}, \text{function}, \text{range}, \text{integer}, \text{perturb}) \rightarrow \text{void}
\]
\[
\text{externalplot}(\text{filename}, \text{mode}, \text{function}, \text{range}, \text{precision}, \text{plot mode}, \text{result filename}) : (\text{string}, \text{absolute|relative}, \text{function}, \text{range}, \text{integer}, \text{file|postscript|postscriptfile}, \text{string}) \rightarrow \text{void}
\]
\[
\text{externalplot}(\text{filename}, \text{mode}, \text{function}, \text{range}, \text{precision}, \text{perturb}, \text{plot mode}, \text{result filename}) : (\text{string}, \text{absolute|relative}, \text{function}, \text{range}, \text{integer}, \text{perturb}, \text{file|postscript|postscriptfile}, \text{string}) \rightarrow \text{void}
\]

50
Description:

- The command `externalplot` plots the error of an external function evaluation code sequence implemented in the object file named `filename` with regard to the function `function`. If `mode` evaluates to `absolute`, the difference of both functions is considered as an error function; if `mode` evaluates to `relative`, the difference is divided by the function `function`. The resulting error function is plotted on all floating-point numbers with `precision` significant mantissa bits in the range `range`. If the sixth argument of the command `externalplot` is given a `perturb`, each of these floating-point numbers is perturbed by a random value that is uniformly distributed in ±1ulp around the original `precision` bit floating-point variable.

If a sixth and seventh argument, respectively a seventh and eighth argument in the presence of `perturb` as a sixth argument, are given that evaluate to a variable of type `file`, `postscript`, `postscriptfile` respectively to a character sequence of type `string`, `externalplot` will plot (additionally) to a file in the same way as the command `plot` does. See `plot` for details.

The external function evaluation code given in the object file name `filename` is supposed to define a function name `f` as follows (here in C syntax): `void f(mpfr rop, mpfr op)`. This function is supposed to evaluate `op` with an accuracy corresponding to the precision of `rop` and assign this value to `rop`.

Example 1:

```bash
> bashexecute("gcc -fPIC -c externalplotexample.c");
> bashexecute("gcc -shared -o externalplotexample externalplotexample.o -lgmp -lmpfr");
> externalplot("./externalplotexample",relative,exp(x),[-1/2;1/2],12,perturb);
```

See also: `plot`, `asciplot`, `perturb`, `absolute`, `relative`, `file`, `postscript`, `postscriptfile`, `bashexecute`, `externalproc`, `library`.

8.52 externalproc

Name: `externalproc` binds an external code to a Sollya procedure

Usage:

```plaintext
externalproc(identifier, filename, argumenttype − > resulttype) : (identifier type, string, type type, type type) → void
```

Parameters:

- `identifier` represents the identifier the code is to be bound to
- `filename` of type `string` represents the name of the object file where the code of procedure can be found
- `argumenttype` represents a definition of the types of the arguments of the Sollya procedure and the external code
- `resulttype` represents a definition of the result type of the external code

Description:

- `externalproc` allows for binding the Sollya identifier `identifier` to an external code. After this binding, when Sollya encounters `identifier` applied to a list of actual parameters, it will evaluate these parameters and call the external code with these parameters. If the external code indicated success, it will receive the result produced by the external code, transform it to Sollya's internal representation and return it.
In order to allow correct evaluation and typing of the data in parameter and in result to be passed to and received from the external code, \texttt{externalproc} has a third parameter \texttt{argumenttype \rightarrow resulttype}. Both \texttt{argumenttype} and \texttt{resulttype} are one of \texttt{void}, constant, function, range, integer, string, boolean, list of constant, list of function, list of range, list of integer, list of string, list of boolean.

If upon a usage of a procedure bound to an external procedure the type of the actual parameters given or its number is not correct, \texttt{Sollya} produces a type error. An external function not applied to arguments represents itself and prints out with its argument and result types.

The external function is supposed to return an integer indicating success. It returns its result depending on its \texttt{Sollya} result type as follows. Here, the external procedure is assumed to be implemented as a C function.

If the \texttt{Sollya} result type is \texttt{void}, the C function has no pointer argument for the result. If the \texttt{Sollya} result type is constant, the first argument of the C function is of C type \texttt{mpfr_t *}, the result is returned by affecting the MPFR variable. If the \texttt{Sollya} result type is function, the first argument of the C function is of C type \texttt{node **}, the result is returned by the \texttt{node *} pointed with a new \texttt{node *}. If the \texttt{Sollya} result type is range, the first argument of the C function is of C type \texttt{mpfi_t *}, the result is returned by affecting the MPFI variable. If the \texttt{Sollya} result type is integer, the first argument of the C function is of C type \texttt{int *}, the result is returned by affecting the int variable. If the \texttt{Sollya} result type is string, the first argument of the C function is of C type \texttt{char **}, the result is returned by the \texttt{char *} pointed with a new \texttt{char *}. If the \texttt{Sollya} result type is boolean, the first argument of the C function is of C type \texttt{int *}, the result is returned by affecting the int variable with a boolean value. If the \texttt{Sollya} result type is list of type, the first argument of the C function is of C type \texttt{chain **}, the result is returned by the \texttt{chain *} pointed with a new \texttt{chain *}. This chain contains for \texttt{Sollya} type constant pointers \texttt{mpfr_t *} to new MPFR variables, for \texttt{Sollya} type function pointers \texttt{node *} to new nodes, for \texttt{Sollya} type range pointers \texttt{mpfi_t *} to new MPFI variables, for \texttt{Sollya} type integer pointers \texttt{int *} to new int variables for \texttt{Sollya} type string pointers \texttt{char *} to new \texttt{char *} variables and for \texttt{Sollya} type boolean pointers \texttt{int *} to new int variables representing boolean values.

The external procedure affects its possible pointer argument if and only if it succeeds. This means, if the function returns an integer indicating failure, it does not leak any memory to the encompassing environment.

The external procedure receives its arguments as follows: If the \texttt{Sollya} argument type is \texttt{void}, no argument array is given. Otherwise the C function receives a C \texttt{void **} argument representing an array of size equal to the arity of the function where each entry (of C type \texttt{void *}) represents a value with a C type depending on the corresponding \texttt{Sollya} type. If the \texttt{Sollya} type is constant, the C type the \texttt{void *} is to be casted to is \texttt{mpfr_t *}. If the \texttt{Sollya} type is function, the C type the \texttt{void *} is to be casted to is \texttt{node *}. If the \texttt{Sollya} type is range, the C type the \texttt{void *} is to be casted to is \texttt{mpfi_t *}. If the \texttt{Sollya} type is integer, the C type the \texttt{void *} is to be casted to is \texttt{int *}. If the \texttt{Sollya} type is string, the C type the \texttt{void *} is to be casted to is \texttt{char *}. If the \texttt{Sollya} type is boolean, the C type the \texttt{void *} is to be casted to is \texttt{chain *}. Here depending on type, the values in the chain are to be casted to \texttt{mpfr_t *} for \texttt{Sollya} type constant, \texttt{node *} for \texttt{Sollya} type function, \texttt{mpfi_t *} for \texttt{Sollya} type range, \texttt{int *} for \texttt{Sollya} type integer, \texttt{char *} for \texttt{Sollya} type string and \texttt{int *} for \texttt{Sollya} type boolean.

The external procedure is not supposed to alter the memory pointed by its array argument \texttt{void **}.

In both directions (argument and result values), empty lists are represented by \texttt{chain * NULL} pointers.

In contrast to internal procedures, externally bounded procedures can be considered as objects inside \texttt{Sollya} that can be assigned to other variables, stored in list etc.

Example 1:
bashexecute("gcc -fPIC -Wall -c externalprocexample.c");
bashexecute("gcc -fPIC -shared -o externalprocexample externalprocexample.o");

externalproc(foo, "./externalprocexample", (integer, integer) -> integer);
foo;
foo(integer, integer) -> integer
foo(5, 6);
11
verbosity = 1!;
foo();
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
a = foo;
a(5,6);
11

See also: library (8.79), externalplot (8.51), bashexecute (8.15), void (8.158), constant (8.23),
function (8.61), range (8.119), integer (8.73), string (8.144), boolean (8.17), list of (8.80)

8.53 false
Name: false
the boolean value representing the false.

Description:

- false is the usual boolean value.

Example 1:

> true && false;
false
> 2<1;
false

See also: true (8.155), && (8.6), || (8.97)

8.54 file
Name: file
special value for commands plot and externalplot

Description:

- file is a special value used in commands plot and externalplot to save the result of the command in a data file.
- As any value it can be affected to a variable and stored in lists.

Example 1:

> savemode=file;
> name="plotSinCos";
> plot(sin(x),0,cos(x),[-Pi,Pi],savemode, name);

See also: externalplot (8.51), plot (8.101), postscript (8.104), postscriptfile (8.105)
8.55 findzeros

Name: findzeros

gives a list of intervals containing all zeros of a function on an interval.

Usage:

\[
\text{findzeros}(f, I) : (\text{function}, \text{range}) \rightarrow \text{list}
\]

Parameters:

- \( f \) is a function.
- \( I \) is an interval.

Description:

- \( \text{findzeros}(f, I) \) returns a list of intervals \( I_1, \ldots, I_n \) such that, for every zero \( z \) of \( f \), there exists some \( k \) such that \( z \in I_k \).
- The list may contain intervals \( I_k \) that do not contain any zero of \( f \). An interval \( I_k \) may contain many zeros of \( f \).
- This command is meant for cases when safety is critical. If you want to be sure not to forget any zero, use \( \text{findzeros} \). However, if you just want to know numerical values for the zeros of \( f \), \( \text{dirtyfindzeros} \) should be quite satisfactory and a lot faster.
- If \( \delta \) denotes the value of global variable \( \text{diam} \), the algorithm ensures that for each \( k \), \( |I_k| \leq \delta \cdot |I| \).
- The algorithm used is basically a bisection algorithm. It is the same algorithm that the one used for \( \text{infnorm} \). See the help page of this command for more details. In short, the behavior of the algorithm depends on global variables \( \text{prec}, \text{diam}, \text{taylorrecursions} \) and \( \text{hopitalrecursions} \).

Example 1:

\[
\begin{align*}
> & \text{findzeros}(\sin(x), [-5;5]); \\
& \quad \left[ [-3.14208984375; -3.140869140625], [-1.220703125e-3; 1.220703125e-3], [3.140869140625; 3.14208984375] \right] \\
> & \text{diam}=1e-10!; \\
> & \text{findzeros}(\sin(x), [-5;5]); \\
& \quad \left[ [-3.1415926537108187198638916015625; -3.141592653692865525563717041015625], [-1.16415321826934814453125e-9; 1.16415321826934814453125e-9], [3.1415926537108187198638916015625; 3.1415926537108187198638916015625] \right]
\end{align*}
\]

See also: \( \text{dirtyfindzeros} \) (8.32), \( \text{infnorm} \) (8.72), \( \text{prec} \) (8.108), \( \text{diam} \) (8.30), \( \text{taylorrecursions} \) (8.152), \( \text{hopitalrecursions} \) (8.68)

8.56 fixed

Name: fixed

indicates that fixed-point formats should be used for \( \text{fpminimax} \)

Usage:

\[
\text{fixed} : \text{fixed|floating}
\]

Description:

- The use of \( \text{fixed} \) in the command \( \text{fpminimax} \) indicates that the list of formats given as argument is to be considered as a list of fixed-point formats. See \( \text{fpminimax} \) for details.

Example 1:
See also: fpminimax [8.59], floating [8.57]

8.57 floating

Name: floating
indicates that floating-point formats should be used for fpminimax

Usage:

\[
\text{floating} : \text{fixed|floating}
\]

Description:

- The use of floating in the command fpminimax indicates that the list of formats given as argument is to be considered as a list of floating-point formats. See fpminimax for details.

Example 1:

\[
> \text{fpminimax}(\cos(x), 6, [[32,32,32,32,32,32], [-1;1], \text{fixed});
0.999999748077243565130615234375 + x^2 * (-0.49999286932870745658874511711875 +
\]
\]
\[
x^2 * (4.16335149202498581336697509765625e-2 + x^2 * (-1.3382240880759946853595375e-3))
\]

See also: fpminimax [8.59], floating [8.57]

8.58 floor

Name: floor
the usual function floor.

Description:

- floor is defined as usual: floor(x) is the greatest integer y such that y \leq x.
- It is defined for every real number x.

See also: ceil [8.19]

8.59 fpminimax

Name: fpminimax
computes a good polynomial approximation with fixed-point or floating-point coefficients

Usage:

\[
\text{fpminimax}(f, n, \text{formats}, \text{range}, \text{indic1}, \text{indic2}, \text{indic3}, P) : (\text{function, integer, list, range,}
\]
\[
\text{absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative |}
\]
\[
\text{fixed|floating | function, function}) \rightarrow \text{function}
\]
\[
\text{fpminimax}(f, \text{monomials, formats, range, indic1, indic2, indic3, P}) : (\text{function, list, list, range,}
\]
\[
\text{absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative |}
\]
\[
\text{fixed|floating | function, function}) \rightarrow \text{function}
\]

55
\texttt{fpminimax}(f, n, formats, L, indic1, indic2, indic3, P) : (function, integer, list, list, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, function) \rightarrow function

\texttt{fpminimax}(f, monomials, formats, L, indic1, indic2, indic3, P) : (function, list, list, list, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, function) \rightarrow function

Parameters:

- \(f\) is the function to be approximated
- \(n\) is the degree of the polynomial that must approximate \(f\)
- \(monomials\) is the list of monomials that must be used to represent the polynomial that approximates \(f\)
- \(formats\) is a list indicating the formats that the coefficients of the polynomial must have
- \(range\) is the interval where the function must be approximated
- \(L\) is a list of interpolation points used by the method
- \(indic1\) (optional) is one of the optional indication parameters. See the detailed description below.
- \(indic2\) (optional) is one of the optional indication parameters. See the detailed description below.
- \(indic3\) (optional) is one of the optional indication parameters. See the detailed description below.
- \(P\) (optional) is the minimax polynomial to be considered for solving the problem.

Description:

- \texttt{fpminimax} uses a heuristic (but practically efficient) method to find a good polynomial approximation of a function \(f\) on an interval \(range\). It implements the method published in the article: Efficient polynomial \(L^\infty\)-approximations
  Nicolas Brisebarre and Sylvain Chevillard
  Proceedings of the 18th IEEE Symposium on Computer Arithmetic (ARITH 18)
  pp. 169-176

- The basic usage of this command is \texttt{fpminimax}(f, n, formats, range). It computes a polynomial approximation of \(f\) with degree at most \(n\) on the interval \(range\). \(formats\) is a list of integers or format types (such as \texttt{double}, \texttt{doubledouble}, etc.). The polynomial returned by the command has its coefficients that fit the formats indications. For instance, if \texttt{formats}[0] is 35, the coefficient of degree 0 of the polynomial will fit a floating-point format of 35 bits. If \texttt{formats}[1] is D, the coefficient of degree 1 will be representable by a floating-point number with a precision of 53 bits (that is not necessarily an IEEE double precision number. See the remark below), etc.

- The second argument may be either an integer or a list of integers interpreted as the list of desired monomials. For instance, the list \([0, 2, 4, 6]\) indicates that the polynomial must be even and of degree at most 6. Giving an integer \(n\) as second argument is equivalent as giving \([0, \ldots, n]\). The list of format is interpreted with respect to the list of monomials. For instance, if the list of monomials is \([0, 2, 4, 6]\) and the list of formats is \([161, 107, 53, 24]\), the coefficients of degree 0 is searched as a floating-point number with precision 161, the coefficient of degree 2 is searched as a number of precision 107, and so on.

- The list of formats may contain either integers or format types (\texttt{double}, \texttt{doubledouble}, \texttt{triple-double} and \texttt{doubleextended}). The list may be too big or even infinite. Only the first indications will be considered. For instance, for a degree \(n\) polynomial, \texttt{formats}[n + 1] and above will be discarded. This lets one use elliptical indications for the last coefficients.

- The floating-point coefficients considered by \texttt{fpminimax} do not have an exponent range. In particular, in the format list, \texttt{double} or 53 does not imply that the corresponding coefficient is an IEEE-754 double.
By default, the list of formats is interpreted as a list of floating-point formats. This may be changed by passing `fixed` as an optional argument (see below). Let us take an example: `fpminimax(f, 2, [107, DD, 53], [0;1])`. Here the optional argument is missing (we could have set it to `floating`). Thus, `fpminimax` will search for a polynomial of degree 2 with a constant coefficient that is a 107 bits floating-point number, etc.

Currently, `doubledouble` is just a synonym for 107 and `tripledouble` a synonym for 161. This behavior may change in the future (taking into account the fact that some double-doubles are not representable with 107 bits).

Second example: `fpminimax(f, 2, [25, 18, 30], [0;1], fixed)`. In this case, `fpminimax` will search for a polynomial of degree 2 with a constant coefficient of the form \( m/2^{25} \) where \( m \) is an integer. In other words, it is a fixed-point number with 25 bits after the point. Note that even with argument `fixed`, the formats list is allowed to contain `double`, `doubledouble` or `tripledouble`. In this case, it is just a synonym for 53, 107 or 161. This is deprecated and may change in the future.

The fourth argument may be a range or a list. Lists are for advanced users that know what they are doing. The core of the method is a kind of approximated interpolation. The list given here is a list of points that must be considered for the interpolation. It must contain at least as many points as unknown coefficients. If you give a list, it is also recommended that you provide the minimax polynomial as last argument. If you give a range, the list of points will be automatically computed.

The fifth, sixth and seventh arguments are optional. By default, `fpminimax` will approximate \( f \) optimizing the relative error, and interpreting the list of formats as a list of floating-point formats. This default behavior may be changed with these optional arguments. You may provide zero, one, two or three of the arguments and in any order. This lets the user indicate only the non-default arguments.

The three possible arguments are:

- `relative` or `absolute`: the error to be optimized;
- `floating` or `fixed`: formats of the coefficients;
- a constrained part \( q \).

The constrained part lets the user assign in advance some of the coefficients. For instance, for approximating \( \exp(x) \), it may be interesting to search for a polynomial \( p \) of the form

\[
p = 1 + x + \frac{x^2}{2} + a_3x^3 + a_4x^4.
\]

Thus, there is a constrained part \( q = 1 + x + x^2/2 \) and the unknown polynomial should be considered in the monomial basis \([3,4]\). Calling `fpminimax` with monomial basis \([3,4]\) and constrained part \( q \), will return a polynomial with the right form.

The last argument is for advanced users. It is the minimax polynomial that approximates the function \( f \) in the monomial basis. If it is not given this polynomial will be automatically computed by `fpminimax`.

This minimax polynomial is used to compute the list of interpolation points required by the method. In general, you do not have to provide this argument. But if you want to obtain several polynomials of the same degree that approximate the same function on the same range, just changing the formats, you should probably consider computing only once the minimax polynomial and the list of points instead of letting `fpminimax` recompute them each time.

Note that in the case when a constrained part is given, the minimax polynomial must take it into account. For instance, in the previous example, the minimax would be obtained by the following command:

\[
P = \text{remez}(1-(1+x+x^2/2)/\exp(x), [3,4], \text{range}, 1/\exp(x));
\]

Note that the constrained part is not to be added to \( P \).
• Note that \texttt{fpminimax} internally computes a minimax polynomial (using the same algorithm as \texttt{remez} command). Thus \texttt{fpminimax} may encounter the same problems as \texttt{remez}. In particular, it may be very long when Haar condition is not fulfilled. Another consequence is that currently \texttt{fpminimax} has to be run with a sufficiently high precision.

Example 1:

\begin{verbatim}
> P = fpminimax(cos(x),6,[[DD, DD, D...]],[-1b-5;1b-5]);
> printexpansion(P);
(0x3ff0000000000000 + 0xbc09fda20235c100) + x * ((0x3b29ecd485d34781 + 0xb7c1cbc971529754) + x * (0xbfdfcfa411931b08 + x * (0xbfdfffffffffff98 + x * (0xbbfa6e0b3183cb0d + x * (0x3fa5555555145337 + x * (0x3ca3540480618939 + x * 0xbf56c138142d8c3b)))))
\end{verbatim}

Example 2:

\begin{verbatim}
> P = fpminimax(sin(x),6,[32...],[-1b-5;1b-5], fixed, absolute);
> display = powers!;
> P;
 x * (1 + x^2 * (-357913941 * 2^(-31) + x^2 * 35789873 * 2^(-32)))
\end{verbatim}

Example 3:

\begin{verbatim}
> P = fpminimax(exp(x), [3,4], [D,24], [-1/256; 1/246], 1+x+x^2/2);
> display = powers!;
> P;
 1 + x * (1 + x * (1 * 2^(-1) + x * (37530022501191 * 2^(-51) + x * 5592621 * 2^(-27))))
\end{verbatim}

Example 4:

\begin{verbatim}
> f = cos(exp(x));
> pstar = remez(f, 5, [-1b-7;1b-7]);
> listpoints = dirtyfindzeros(f-pstar, [-1b-7; 1b-7]);
> P1 = fpminimax(f, 5, [[DD...]], listpoints, absolute, default, default, pstar);
> P2 = fpminimax(f, 5, [[...]], listpoints, absolute, default, default, pstar);
> P3 = fpminimax(f, 5, [[D, D, D, 24...]], listpoints, absolute, default, default, default, pstar);
> print("Error of pstar: ", dirtyinfnorm(f-pstar, [-1b-7; 1b-7]));
Error of pstar: 7.9048441305459735102879831325718747183089581485922e-16
> print("Error of P1: ", dirtyinfnorm(f-P1, [-1b-7; 1b-7]));
Error of P1: 7.9048441305459735102879831325718747183089581485922e-16
> print("Error of P2: ", dirtyinfnorm(f-P2, [-1b-7; 1b-7]));
Error of P2: 8.2477144579950871061147021597406077993657714576238e-16
> print("Error of P3: ", dirtyinfnorm(f-P3, [-1b-7; 1b-7]));
Error of P3: 1.0845427715699328259370115841863009789063333951055e-15
\end{verbatim}

8.60 \texttt{fullparentheses}

Name: \texttt{fullparentheses}
activates, deactivates or inspects the state variable controlling output with full parenthesising

Usage:
fullparentheses = activation value : on/off → void
fullparentheses = activation value ! : on/off → void

Parameters:

- *activation value* represents **on** or **off**, i.e. activation or deactivation

Description:

- An assignment fullparentheses = activation value, where activation value is one of **on** or **off**, activates respectively deactivates the output of expressions with full parenthesising. In full parenthesising mode, Sollya commands like **print**, **write** and the implicit command when an expression is given at the prompt will output expressions with parenthesising at all places where it is necessary for expressions containing infix operators to be parsed back with the same result. Otherwise parentheses around associative operators are omitted.

If the assignment fullparentheses = activation value is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

Example 1:

```plaintext
> autosimplify = off!;
> fullparentheses = off;
Full parentheses mode has been deactivated.
> print(1 + 2 + 3);
1 + 2 + 3
> fullparentheses = on;
Full parentheses mode has been activated.
> print(1 + 2 + 3);
(1 + 2) + 3
```

See also: **print** (8.111), **write** (8.160), **autosimplify** (8.14)

### 8.61 function

Name: **function**
keyword representing a function type

Usage:

```plaintext
function : type type
```

Description:

- **function** represents the function type for declarations of external procedures by means of **externalproc**.

  Remark that in contrast to other indicators, type indicators like **function** cannot be handled outside the **externalproc** context. In particular, they cannot be assigned to variables.

See also: **externalproc** (8.52), **boolean** (8.17), **constant** (8.23), **integer** (8.73), **list of** (8.80), **range** (8.119), **string** (8.144)

### 8.62 ge

Name: >=
greater-than-or-equal-to operator

Usage:
Parameters:

- `expr1` and `expr2` represent constant expressions

Description:

- The operator `>=` evaluates to true iff its operands `expr1` and `expr2` evaluate to two floating-point numbers `a_1` respectively `a_2` with the global precision `prec` and `a_1` is greater than or equal to `a_2`. The user should be aware of the fact that because of floating-point evaluation, the operator `>=` is not exactly the same as the mathematical operation `greater-than-or-equal-to`.

Example 1:

```plaintext
> 5 >= 4;
true
> 5 >= 5;
true
> 5 >= 6;
false
> exp(2) >= exp(1);
true
> log(1) >= exp(2);
false
```

Example 2:

```plaintext
> prec = 12;
The precision has been set to 12 bits.
> 16384.1 >= 16385.1;
true
```

See also: ```8.41; != (8.91); >= (8.63); <= (8.77); < (8.85); ! (8.93); && (8.6); || (8.97); prec (8.108)```
> 5 > 4;  
true  
> 5 > 5;  
false  
> 5 > 6;  
false  
> exp(2) > exp(1);  
true  
> log(1) > exp(2);  
false

Example 2:

> prec = 12;  
The precision has been set to 12 bits.  
> 16385.1 > 16384.1;  
false

See also: == (8.41),  
! (8.91),  
>= (8.62),  
<= (8.77),  
< (8.85),  
! (8.93),  
&& (8.6),  
|| (8.97),  
prec (8.108)

8.64  guessdegree

Name: guessdegree  
returns the minimal degree needed for a polynomial to approximate a function with a certain error on an interval.

Usage:  
guessdegree(f,I,eps,w) : (function, range, constant, function) → range

Parameters:  
• f is the function to be approximated.  
• I is the interval where the function must be approximated.  
• eps is the maximal acceptable error.  
• w (optional) is a weight function. Default is 1.

Description:  
• guessdegree tries to find the minimal degree needed to approximate f on I by a polynomial with an infinite error not greater than eps. More precisely, it finds n minimal such that there exists a polynomial p of degree n such that \|pw - f\|_\infty < eps.  
• guessdegree returns an interval: for common cases, this interval is reduced to a single number (e.g. the minimal degree). But in certain cases, guessdegree does not succeed in finding the minimal degree. In such cases the returned interval is of the form \([n, p]\) such that:  
  – no polynomial of degree n − 1 gives an error less than eps.  
  – there exists a polynomial of degree p giving an error less than eps.

Example 1:

> guessdegree(exp(x),[-1;1],1e-10);  
[10;10]

Example 2:

> guessdegree(1,[-1;1],1e-8,1/exp(x));  
[8;9]

See also: dirtyinfnorm (8.33), remez (8.125)
8.65 head

Name: head

gives the first element of a list.

Usage:

\[
\text{head}(L) : \text{list} \rightarrow \text{any type}
\]

Parameters:

- \( L \) is a list.

Description:

- \( \text{head}(L) \) returns the first element of the list \( L \). It is equivalent to \( L[0] \).
- If \( L \) is empty, the command will fail with an error.

Example 1:

```plaintext
> \text{head}([[1,2,3]]);
1
> \text{head}([[1,2\ldots]])
1
```

See also: tail (8.148)

8.66 hexadecimal

Name: hexadecimal

special value for global state display

Description:

- \( \text{hexadecimal} \) is a special value used for the global state \( \text{display} \). If the global state \( \text{display} \) is equal to \( \text{hexadecimal} \), all data will be output in hexadecimal C99/IEEE 754R notation.

As any value it can be affected to a variable and stored in lists.

See also: decimal (8.26), dyadic (8.40), powers (8.107), binary (8.16)

8.67 honorcoeffprec

Name: honorcoeffprec

indicates the (forced) honoring the precision of the coefficients in \( \text{implementpoly} \)

Usage:

\[
\text{honorcoeffprec} : \text{honorcoeffprec}
\]

Description:

- Used with command \( \text{implementpoly} \), \( \text{honorcoeffprec} \) makes \( \text{implementpoly} \) honor the precision of the given polynomial. This means if a coefficient needs a double-double or a triple-double to be exactly stored, \( \text{implementpoly} \) will allocate appropriate space and use a double-double or triple-double operation even if the automatic (heuristic) determination implemented in command \( \text{implementpoly} \) indicates that the coefficient could be stored on less precision or, respectively, the operation could be performed with less precision. See \( \text{implementpoly} \) for details.

Example 1:
> verbosity = 1;
> q = implementpoly(1 - simplify(TD(1/6)) * x^2,[-1b-10;1b-10],1b-60,DD,"p","implementation.c");
> r = implementpoly(1 - simplify(TD(1/6)) * x^2,[-1b-10;1b-10],1b-60,DD,"p","implementation.c",honorcoeffprec);

Warning: the inferred precision of the 2nd coefficient of the polynomial is greater than the necessary precision computed for this step. This may make the automatic determination of precisions useless.

> printexpansion(q);
0x3ff0000000000000 + x^2 * 0xbfc5555555555555
> printexpansion(r);
0x3ff0000000000000 + x^2 * (0xbfc5555555555555 + 0xbc65555555555555 + 0xb905555555555555)

See also: implementpoly (8.70), printexpansion (8.112)

8.68 hospitalrecursions

Name: hospitalrecursions
controls the number of recursion steps when applying L'Hopital's rule.

Description:

- **hospitalrecursions** is a global variable. Its value represents the number of steps of recursion that are tried when applying L'Hopital's rule. This rule is applied by the interval evaluator present in the core of Sollya (and particularly visible in commands like infnorm).

- If an expression of the form \( f/g \) has to be evaluated by interval arithmetic on an interval \( I \) and if \( f \) and \( g \) have a common zero in \( I \), a direct evaluation leads to NaN. Sollya implements a safe heuristic to avoid this, based on L'Hopital's rule: in such a case, it can be shown that \( (f/g)(I) \subseteq (f'/g')(I) \). Since the same problem may hold for \( f'/g' \), the rule is applied recursively. The number of step in this recursion process is controlled by **hospitalrecursions**.

- Setting **hospitalrecursions** to 0 makes Sollya use this rule only one time; setting it to 1 makes Sollya use the rule two times, and so on. In particular: the rule is always applied at least once, if necessary.

Example 1:

> hospitalrecursions=0;
The number of recursions for Hopital's rule has been set to 0.
> evaluate(log(1+x)^2/x^2,[-1/2; 1]);
\([-@Inf@;@Inf@] \)
> hospitalrecursions=1;
The number of recursions for Hopital's rule has been set to 1.
> evaluate(log(1+x)^2/x^2,[-1/2; 1]);
\([-2.5225887223978123766892848583270627230200053744108;6.772588722397812376689284858327062723020005374411] \)
8.69 horner

Name: horner
brings all polynomial subexpressions of an expression to Horner form

Usage:

\[
\text{horner}(\text{function}) : \text{function} \rightarrow \text{function}
\]

Parameters:

- \text{function} represents the expression to be rewritten in Horner form

Description:

- The command \text{horner} rewrites the expression representing the function \text{function} in a way such that all polynomial subexpressions (or the whole expression itself, if it is a polynomial) are written in Horner form. The command \text{horner} does not endanger the safety of computations even in Sollya’s floating-point environment: the function returned is mathematically equal to the function \text{function}.

Example 1:

```plaintext
> print(horner(1 + 2 * x + 3 * x^2));
1 + x * (2 + x * 3)
> print(horner((x + 1) ^ 7));
1 + x * (7 + x * (21 + x * (35 + x * (35 + x * (21 + x * (7 + x))))))
```

Example 2:

```plaintext
> print(horner(exp((x + 1) ^ 5) - log(asin(x + x^3) + x));
exp(1 + x * (5 + x * (10 + x * (10 + x * (5 + x))))) - log(asin(x * (1 + x^2)) + x)
```

See also: canonical [8.18], print [8.11]

8.70 implementpoly

Name: implementpoly
implements a polynomial using double, double-double and triple-double arithmetic and generates a Gappa proof

Usage:

\[
\text{implementpoly}(\text{polynomial}, \text{range}, \text{error bound}, \text{format}, \text{functionname}, \text{filename}) : (\text{function}, \text{range}, \text{constant}, \text{D}\text{ouble}\text{Double}|\text{DD}|\text{doubledouble}|\text{TD}|\text{tripledouble}, \text{string}, \text{string}) \rightarrow \text{function}
\]

\[
\text{implementpoly}(\text{polynomial}, \text{range}, \text{error bound}, \text{format}, \text{functionname}, \text{filename}, \text{honor coefficient precisions}) : (\text{function}, \text{range}, \text{constant}, \text{D}\text{ouble}\text{Double}|\text{DD}|\text{doubledouble}|\text{TD}|\text{tripledouble}, \text{string}, \text{string}, \text{honorcoeffprec}) \rightarrow \text{function}
\]

\[
\text{implementpoly}(\text{polynomial}, \text{range}, \text{error bound}, \text{format}, \text{functionname}, \text{filename}, \text{proof filename}) : (\text{function}, \text{range}, \text{constant}, \text{D}\text{ouble}\text{Double}|\text{DD}|\text{doubledouble}|\text{TD}|\text{tripledouble}, \text{string}, \text{string}, \text{string}) \rightarrow \text{function}
\]

Description:

- The command \text{implementpoly} implements the polynomial \text{polynomial} in range \text{range} as a function called \text{functionname} in C code using double, double-double and triple-double arithmetic in a way that the rounding error (estimated at its first order) is bounded by \text{error bound}. The produced code is output in a file named \text{filename}. The argument \text{format} indicates the double, double-double or
triple-double format of the variable in which the polynomial varies, influencing also in the signature of the C function.

If a seventh or eighth argument proof filename is given and if this argument evaluates to a variable of type string, the command implementpoly will produce a Gappa proof that the rounding error is less than the given bound. This proof will be output in Gappa syntax in a file name proof filename.

The command implementpoly returns the polynomial that has been implemented. As the command implementpoly tries to adapt the precision needed in each evaluation step to its strict minimum and as it applies renormalization to double-double and triple-double precision coefficients to bring them to a round-to-nearest expansion form, the polynomial return may differ from the polynomial polynomial. Nevertheless the difference will be small enough that the rounding error bound with regard to the polynomial polynomial (estimated at its first order) will be less than the given error bound.

If a seventh argument honor coefficient precisions is given and evaluates to a variable honorcoeffprec of type honorcoeffprec, implementpoly will honor the precision of the given polynomial polynomials. This means if a coefficient needs a double-double or a triple-double to be exactly stored, implementpoly will allocate appropriate space and use a double-double or triple-double operation even if the automatic (heuristic) determination implemented in command implementpoly indicates that the coefficient could be stored on less precision or, respectively, the operation could be performed with less precision. The use of honorcoeffprec has advantages and disadvantages. If the polynomial polynomial given has not been determined by a process considering directly polynomials with floating-point coefficients, honorcoeffprec should not be indicated. The implementpoly command can then determine the needed precision using the same error estimation as used for the determination of the precisions of the operations. Generally, the coefficients will get rounded to double, double-double and triple-double precision in a way that minimizes their number and respects the rounding error bound error bound. Indicating honorcoeffprec may in this case short-circuit most precision estimations leading to sub-optimal code. On the other hand, if the polynomial polynomial has been determined with floating-point precisions in mind, honorcoeffprec should be indicated because such polynomials often are very sensitive in terms of error propagation with regard to their coefficients’ values. Indicating honorcoeffprec prevents the implementpoly command from rounding the coefficients and altering by many orders of magnitude approximation error of the polynomial with regard to the function it approximates.

The implementer behind the implementpoly command makes some assumptions on its input and verifies them. If some assumption cannot be verified, the implementation will not succeed and implementpoly will evaluate to a variable error of type error. The same behaviour is observed if some file is not writable or some other side-effect fails, e.g. if the implementer runs out of memory.

As error estimation is performed only on the first order, the code produced by the implementpoly command should be considered valid iff a Gappa proof has been produced and successfully run in Gappa.

Example 1:
Example 2:

```c
void p(double *p_resh, double x) {
    double p_x_0_pow2h;
    p_x_0_pow2h = x * x;
    double p_t_1_0h;
    double p_t_2_0h;
    double p_t_3_0h;
    double p_t_4_0h;
    double p_t_5_0h;
    p_t_1_0h = p_coeff_4h;
    p_t_2_0h = p_t_1_0h * p_x_0_pow2h;
    p_t_3_0h = p_coeff_2h + p_t_2_0h;
    p_t_4_0h = p_t_3_0h * p_x_0_pow2h;
    p_t_5_0h = p_coeff_0h + p_t_4_0h;
    *p_resh = p_t_5_0h;
}
```

Example 3:
> verbosity = 1!
> q = implementpoly(1 - simplify(TD(1/6)) * x^2,[-1b-10;1b-10],1b-60,DD,"p","implementation.c");
Warning: at least one of the coefficients of the given polynomial has been rounded in a way
that the target precision can be achieved at lower cost. Nevertheless, the implemented polynomial
is different from the given one.
> printexpansion(q);
0x3ff0000000000000 + x^2 * 0xbfc5555555555555
> r = implementpoly(1 - simplify(TD(1/6)) * x^2,[-1b-10;1b-10],1b-60,DD,"p","implementation.c",honorcoeffprec);
Warning: the inferred precision of the 2th coefficient of the polynomial is greater than
the necessary precision computed for this step. This may make the automatic determination
of precisions useless.
> printexpansion(r);
0x3ff0000000000000 + x^2 * (0xbfc5555555555555 + 0xbc65555555555555 + 0xb9055555555555555)

Example 4:

Example 4:

See also: 

8.71 inf

Name: inf
gives the lower bound of an interval.

Usage:

inf(I) : range → constant
inf(x) : constant → constant

Parameters:

• I is an interval.
• x is a real number.

Description:

• Returns the lower bound of the interval I. Each bound of an interval has its own precision, so this command is exact, even if the current precision is too small to represent the bound.
• When called on a real number \( x \), \( \inf \) considers it as an interval formed of a single point: \([x, x]\). In other words, \( \inf \) behaves like the identity.

Example 1:

```latex
> \text{inf}([1;3]);
1
> \text{inf}(0);
0
```

Example 2:

```latex
> \text{display=binary!};
> I=[0.11110000011111_2; 1];
> \text{inf}(I);
1.11110000011111_2 * 2^{-1}
> \text{prec=12!};
> \text{inf}(I);
1.11110000011111_2 * 2^{-1}
```

See also: \textit{mid} \(8.87\), \textit{sup} \(8.147\)

8.72 \textit{infnorm}

Name: \textit{infnorm}

computes an interval bounding the infinite norm of a function on an interval.

Usage:

\[
\text{infnorm}(f, I, filename, IList) : (\text{function}, \text{range}, \text{string}, \text{list}) \rightarrow \text{range}
\]

Parameters:

• \( f \) is a function.
• \( I \) is an interval.
• \( filename \) (optional) is the name of the file into a proof will be saved.
• \( IList \) (optional) is a list of intervals to be excluded.

Description:

• \textit{infnorm}(f, range) computes an interval bounding the infinite norm of the given function \( f \) on the interval \( I \), e.g. computes an interval \( J \) such that \( \max_{x \in I} |f(x)| \subseteq J \).

• If \textit{filename} is given, a proof in English will be produced (and stored in file called \textit{filename}) proving that \( \max_{x \in I} |f(x)| \subseteq J \).

• If a list \textit{IList} of intervals \( I_1, \ldots, I_n \) is given, the infinite norm will be computed on \( I (I_1 \cup \ldots \cup I_n) \).

• The function \( f \) is assumed to be at least twice continuous on \( I \). More generally, if \( f \) is \( C^k \), global variables \textit{hospitalrecursions} and \textit{taylorrecursions} must have values not greater than \( k \).

• If the interval is reduced to a single point, the result of \textit{infnorm} is an interval containing the exact absolute value of \( f \) at this point.

• If the interval is not bound, the result will be \([0, +\infty]\) which is true but perfectly useless. \textit{infnorm} is not meant to be used with infinite intervals.

• The result of this command depends on the global variables \textit{prec}, \textit{diam}, \textit{taylorrecursions} and \textit{hospitalrecursions}. The contribution of each variable is not easy even to analyse.
The algorithm uses interval arithmetic with precision \textit{prec}. The precision should thus be set big enough to ensure that no critical cancellation will occur.

When an evaluation is performed on an interval \([a, b]\), if the result is considered being too large, the interval is split into \([a, a + \frac{b-a}{2}]\) and \([a + \frac{b-a}{2}, b]\) and so on recursively. This recursion step is not performed if the \((b-a) < \delta \cdot |I|\) where \(\delta\) is the value of variable \textit{diam}. In other words, \textit{diam} controls the minimum length of an interval during the algorithm.

To perform the evaluation of a function on an interval, Taylor’s rule is applied, e.g. \(f([a, b]) \subseteq f(m) + [a - m, b - m] \cdot f'([a, b])\) where \(m = \frac{a + b}{2}\). This rule is applied recursively \(n\) times where \(n\) is the value of variable \textit{taylorrecursions}. Roughly speaking, the evaluations will avoid decorrelation up to order \(n\).

When a function of the form \(\frac{g}{h}\) has to be evaluated on an interval \([a, b]\) and when \(g\) and \(h\) vanish at a same point \(z\) of the interval, the ratio may be defined even if the expression \(\frac{g(z)}{h(z)} = \frac{0}{0}\) does not make any sense. In this case, L’Hôpital’s rule may be used and \(\left(\frac{g}{h}\right)([a, b]) \subseteq \left(\frac{g'}{h'}\right)([a, b])\). Since the same can occur with the ratio \(\frac{g'}{h'}\), the rule is applied recursively. Variable \textit{hopitalrecursions} controls the number of recursion steps.

The algorithm used for this command is quite complex to be explained here. Please find a complete description in the following article:
S. Chevillard and C. Lauter
A certified infinite norm for the implementation of elementary functions
LIP Research Report number RR2007-26

```

Example 3:

```matlab
> infnorm(exp(x),[-2;3],[[0;1], [2;2.5] |]);
[2.00855369217667740928529654817178969879078385537e1;2.00855369217667740928529654817178969879078385544e1]
```

Example 4:

```matlab
> infnorm(exp(x),[-2;3],"proof.txt", [[0;1], [2;2.5] |]);
[2.00855369217667740928529654817178969879078385537e1;2.00855369217667740928529654817178969879078385544e1]
```

Example 5:

```matlab
> infnorm(exp(x),[1;1]);
[2.71828182845904523536028747135266249775724709369989;2.71828182845904523536028747135266249775724709369989]
```

Example 6:

```matlab
> infnorm(exp(x), [log(0);log(1)]);
[0;@Inf@]
```

8.73 integer

Name: integer
keyword representing a machine integer type

Usage:

integer : type type

Description:
• integer represents the machine integer type for declarations of external procedures by means of
  externalproc.
  Remark that in contrast to other indicators, type indicators like integer cannot be handled outside
  the externalproc context. In particular, they cannot be assigned to variables.

See also: externalproc [8.52], boolean [8.17], constant [8.23], function [8.61], list of [8.80], range
 [8.119], string [8.144]

8.74 integral

Name: integral
computes an interval bounding the integral of a function on an interval.

Usage:

integral(f, I) : (function, range) → range

Parameters:
• f is a function.
• I is an interval.

Description:
• integral(f, I) returns an interval J such that the exact value of the integral of f on I lies in J.
  This command is safe but very inefficient. Use dirtyintegral if you just want an approximate
  value.
• The result of this command depends on the global variable diam. The method used is the following:
  I is cut into intervals of length not greater than δ · |I| where δ is the value of global variable diam.
  On each small interval J, an evaluation of f by interval is performed. The result is multiplied by
  the length of J. Finally all values are summed.

Example 1:

```plaintext
> sin(10);
-0.5440211108893698134047476618513772816836430291621
> integral(cos(x),[0;10]);

> diam=1e-5;
> integral(cos(x),[0;10]);
[-0.54432915685955427101857780295936956775293876382777; -0.54371306401249969508039644221927489010425803173555]
```

See also: points [8.103], dirtyintegral [8.34]
8.75 isbound

Name: isbound
indicates whether a variable is bound or not.

Usage:

\[ \text{isbound}(ident) : \text{boolean} \]

Parameters:

\begin{itemize}
  \item \textit{ident} is a name.
\end{itemize}

Description:

\begin{itemize}
  \item \texttt{isbound}(ident) returns a boolean value indicating whether the name \textit{ident} is used or not to represent a variable. It returns true when \textit{ident} is the name used to represent the global variable or if the name is currently used to refer to a (possibly local) variable.
  
  \item When a variable is defined in a block and has not been defined outside, \texttt{isbound} returns true when called inside the block, and false outside. Note that \texttt{isbound} returns true as soon as a variable has been declared with \texttt{var}, even if no value is actually stored in it.
  
  \item If \textit{ident1} is bound to a variable and if \textit{ident2} refers to the global variable, the command \texttt{rename(ident2, ident1)} hides the value of \textit{ident1} which becomes the global variable. However, if the global variable is again renamed, \textit{ident1} gets its value back. In this case, \texttt{isbound}(ident1) returns true. If \textit{ident1} was not bound before, \texttt{isbound}(ident1) returns false after that \textit{ident1} has been renamed.
\end{itemize}

Example 1:

\begin{verbatim}
> isbound(x);
false
> isbound(f);
false
> isbound(g);
false
> f=sin(x);
> isbound(x);
true
> isbound(f);
true
> isbound(g);
false
\end{verbatim}

Example 2:

\begin{verbatim}
> isbound(a);
false
> { var a; isbound(a); };
true
> isbound(a);
false
\end{verbatim}

Example 3:

\begin{verbatim}
> f=sin(x);
> isbound(x);
true
> rename(x,y);
> isbound(x);
false
\end{verbatim}
Example 4:

```plaintext
> x=1;
> f=sin(y);
> rename(y,x);
> f;
  sin(x)
> x;
  x
> isbound(x);
  true
> rename(x,y);
> isbound(x);
  true
> x;
  1
```

See also: `rename` (8.126)

8.76 `isevaluable`

**Name:** `isevaluable`

*tests whether a function can be evaluated at a point*

**Usage:**

```
isevaluable(function, constant) : (function, constant) → boolean
```

**Parameters:**

- `function` represents a function
- `constant` represents a constant point

**Description:**

- `isevaluable` applied to function `function` and a constant `constant` returns a boolean indicating whether or not a subsequent call to `evaluate` on the same function `function` and constant `constant` will produce a numerical result or NaN. I.e. `isevaluable` returns false if `evaluate` will return NaN.

**Example 1:**

```plaintext
> isevaluable(sin(pi * 1/x), 0.75);
  true
> print(evaluate(sin(pi * 1/x), 0.75));
  -0.86602540378443864676372317075293618347140262690518
```

**Example 2:**

```plaintext
> isevaluable(sin(pi * 1/x), 0.5);
  true
> print(evaluate(sin(pi * 1/x), 0.5));
  [-1.72986452514381269516508615031096129542836767991679e-12715; 7.594119820118796314506943145266170603908439067e-12716]
```

**Example 3:**

```plaintext
> isevaluable(sin(pi * 1/x), 0);
  false
> print(evaluate(sin(pi * 1/x), 0));
  [@NaN@; @NaN@]
```

See also: `evaluate` (8.45)
8.77 le
Name: <=
less-than-or-equal-to operator

Usage:

\[ \text{expr1} \leq \text{expr2} : (\text{constant, constant}) \rightarrow \text{boolean} \]

Parameters:

- expr1 and expr2 represent constant expressions

Description:

- The operator \( \leq \) evaluates to true iff its operands expr1 and expr2 evaluate to two floating-point numbers \( a_1 \) respectively \( a_2 \) with the global precision \( \text{prec} \) and \( a_1 \) is less than or equal to \( a_2 \). The user should be aware of the fact that because of floating-point evaluation, the operator \( \leq \) is not exactly the same as the mathematical operation less-than-or-equal-to.

Example 1:

```
> 5 <= 4;
false
> 5 <= 5;
true
> 5 <= 6;
true
> exp(2) <= exp(1);
false
> log(1) <= exp(2);
true
```

Example 2:

```
> prec = 12;
The precision has been set to 12 bits.
> 16385.1 <= 16384.1;
true
```

See also: == (8.41), != (8.91), >= (8.62), > (8.63), < (8.85), || (8.97), && (8.6), prec (8.108)

8.78 length

Name: length

computes the length of a list or string.

Usage:

\[ \text{length}(L) : \text{list} \rightarrow \text{integer} \]
\[ \text{length}(s) : \text{string} \rightarrow \text{integer} \]

Parameters:

- \( L \) is a list.
- \( s \) is a string.

Description:

- length returns the length of a list or a string, e.g. the number of elements or letters.
• The empty list or string have length 0. If \( L \) is an end-elliptic list, \texttt{length} returns +Inf.

Example 1:

```plaintext
> length("Hello World!");
12
```

Example 2:

```plaintext
> length([|1,...,5|]);
5
```

Example 3:

```plaintext
> length([||]);
1
```

Example 4:

```plaintext
> length([|1,2...|]);
@Inf@
```

8.79 library

Name: library

binds an external mathematical function to a variable in Sollya

Usage:

\[
\text{library}(path) : \text{string} \rightarrow \text{function}
\]

Description:

• The command library lets you extends the set of mathematical functions known by Sollya. By default, Sollya knows the most common mathematical functions such as \texttt{exp}, \texttt{sin}, \texttt{erf}, etc. Within Sollya, these functions may be composed. This way, Sollya should satisfy the needs of a lot of users. However, for particular applications, one may want to manipulates other functions such as Bessel functions, or functions defined by an integral or even a particular solution of an ODE.

• library makes it possible to let Sollya know about new functions. In order to let it know, you have to provide an implementation of the function you are interested with. This implementation is a C file containing a function of the form:

```c
int my_ident(mpfi_t result, mpfi_t op, int n)
```

The semantic of this function is the following: it is an implementation of the function and its derivatives in interval arithmetic. my\_ident(result, I, n) shall store in result an enclosure of the image set of the n-th derivative of the function \( f \) over \( I: f^{(n)}(I) \subseteq \text{result} \).

• The integer returned value has no meaning currently.

• You must not provide a non trivial implementation for any \( n \). Most functions of Sollya needs a relevant implementation of \( f, f' \) and \( f'' \). For higher derivatives, its is not so critical and the implementation may just store \([-\infty, +\infty]\) in result whenever \( n > 2 \).

• Note that you should respect somehow MPFI standards in your implementation: result has its own precision and you should perform the intermediate computations so that result is as tighter as possible.

• You can include sollya.h in your implementation and use library functionnalities of Sollya for your implementation.
To bind your function into Sollya, you must use the same identifier as the function name used in your implementation file (my_ident in the previous example).

Example 1:

```bash
> bashexecute("gcc -fPIC -Wall -c libraryexample.c");
> bashexecute("gcc -shared -o libraryexample libraryexample.o -lgmp -lmpfr");
> myownlog = library("./libraryexample");
> evaluate(log(x), 2);
0.693147180559945309417232121458175656807550013436024
> evaluate(myownlog(x), 2);
0.693147180559945309417232121458175656807550013436024
```

See also: [bashexecute](#), [externalproc](#), [externalplot](#)

### 8.80 listof

#### Name:

list of

#### Keyword used in combination with a type keyword

#### Description:

- **list of** is used in combination with one of the following keywords for indicating lists of the respective type in declarations of external procedures using externalproc: boolean, constant, function, integer, range and string.

See also: [externalproc](#), [boolean](#), [constant](#), [function](#), [integer](#), [range](#), [string](#)

### 8.81 log

#### Name:

log

#### natural logarithm.

#### Description:

- **log** is the natural logarithm defined as the inverse of the exponential function: log(y) is the unique real number x such that exp(x) = y.
- It is defined only for y ∈ [0; +∞].

See also: [exp](#), [log2](#), [log10](#)

### 8.82 log10

#### Name:

log10

decimal logarithm.

#### Description:

- **log10** is the decimal logarithm defined by: log10(x) = log(x)/log(10).
- It is defined only for x ∈ [0; +∞].

See also: [log](#), [log2](#)
8.83 log1p

Name: log1p
translated logarithm.

Description:

• log1p is the function defined by log1p(x) = log(1 + x).
• It is defined only for x ∈ [−1; +∞].

See also: log (8.81)

8.84 log2

Name: log2
binary logarithm.

Description:

• log2 is the binary logarithm defined by: log2(x) = log(x)/log(2).
• It is defined only for x ∈ [0; +∞].

See also: log (8.81), log10 (8.82)

8.85 lt

Name: <
less-than operator

Usage: expr1 < expr2 : (constant, constant) → boolean

Parameters:
• expr1 and expr2 represent constant expressions

Description:

• The operator < evaluates to true iff its operands expr1 and expr2 evaluate to two floating-point numbers a1 respectively a2 with the global precision prec and a1 is less than a2. The user should be aware of the fact that because of floating-point evaluation, the operator < is not exactly the same as the mathematical operation less-than.

Example 1:

> 5 < 4;
false
> 5 < 5;
false
> 5 < 6;
true
> exp(2) < exp(1);
false
> log(1) < exp(2);
true

Example 2:
The precision has been set to 12 bits.
false

See also: == (8.41), != (8.91), >= (8.62), > (8.63), <= (8.77), < (8.93), && (8.6), || (8.97), prec (8.108)

## 8.86 mantissa

Name: **mantissa**

returns the integer mantissa of a number.

Usage:

\[
mantissa(x) : constant \to integer
\]

Parameters:

- \(x\) is a dyadic number.

Description:

- \(mantissa(x)\) is by definition \(x\) if \(x\) equals 0, NaN, or Inf.
- If \(x\) is not zero, it can be uniquely written as \(x = m \cdot 2^e\) where \(m\) is an odd integer and \(e\) is an integer. \(mantissa(x)\) returns \(m\).

Example 1:

```plaintext
> a=round(Pi,20,RN);
> e=exponent(a);
> m=mantissa(a);
> m;
411775
> a-m*2^e;
0
```

See also: exponent (8.50), precision (8.109)

## 8.87 mid

Name: **mid**

gives the middle of an interval.

Usage:

\[
mid(I) : range \to constant
\]

mid\((x) : constant \to constant
\]

Parameters:

- \(I\) is an interval.
- \(x\) is a real number.

Description:

- Returns the middle of the interval \(I\). If the middle is not exactly representable at the current precision, the value is returned as an unevaluated expression.
• When called on a real number \( x \), \texttt{mid} considers it as an interval formed of a single point: \( [x, x] \). In other words, \texttt{mid} behaves like the identity.

Example 1:

```plaintext
> mid([1;3]);
2
> mid(17);
17
```

See also: \texttt{inf} \(\text{(8.71)}\), \texttt{sup} \(\text{(8.147)}\)

### 8.88 midpointmode

**Name:** \texttt{midpointmode}

global variable controlling the way intervals are displayed.

**Description:**

- \texttt{midpointmode} is a global variable. When its value is \texttt{off}, intervals are displayed as usual (with the form \([a;b]\)). When its value is \texttt{on}, and if \( a \) and \( b \) have the same first significant digits, the interval in displayed in a way that lets one immediately see the common digits of the two bounds.

- This mode is supported only with \texttt{display} set to \texttt{decimal}. In other modes of display, \texttt{midpointmode} value is simply ignored.

Example 1:

```plaintext
> a = round(Pi,30,RD);
> b = round(Pi,30,RU);
> d = [a,b];
> d;
[3.1415926516056060791015625;3.1415926553308963775634765625]
> midpointmode=on!;
> d;
0.314159265\approx1/6\approx e1
```

See also: \texttt{on} \(\text{(8.96)}\), \texttt{off} \(\text{(8.95)}\), \texttt{roundingwarnings} \(\text{(8.134)}\)

### 8.89 minus

**Name:** \texttt{−}

subtraction function

**Usage:**

\[
\texttt{function1} - \texttt{function2} : (\texttt{function}, \texttt{function}) \rightarrow \texttt{function}
\]

**Parameters:**

- \texttt{function1} and \texttt{function2} represent functions

**Description:**

- \texttt{−} represents the subtraction (function) on reals. The expression \texttt{function1} - \texttt{function2} stands for the function composed of the subtraction function and the two functions \texttt{function1} and \texttt{function2}, where \texttt{function1} is the subtrahend and \texttt{function2} the subtractor.

Example 1:
Example 2:

> x - 2;
-2 + x

Example 3:

> x - x;
0

Example 4:

> diff(sin(x) - exp(x));
\[ \cos(x) - \exp(x) \]

See also: + (8.102), ∗ (8.90), / (8.36), ^ (8.106)

8.90 mult

Name: ∗

multiplication function

Usage:

\[ function1 ∗ function2 : (function, function) → function \]

Parameters:

• function1 and function2 represent functions

Description:

• ∗ represents the multiplication (function) on reals. The expression function1 ∗ function2 stands for the function composed of the multiplication function and the two functions function1 and function2.

Example 1:

> 5 ∗ 2;
10

Example 2:

> x ∗ 2;
x ∗ 2

Example 3:

> x ∗ x;
x^2

Example 4:

> diff(sin(x) ∗ exp(x));
\[ \sin(x) ∗ \exp(x) + \exp(x) ∗ \cos(x) \]

See also: + (8.102), − (8.89), / (8.36), ^ (8.106)
8.91 neq

Name: !=

negated equality test operator

Usage:

\[ expr1 \neq expr2 : (\text{any type, any type}) \rightarrow \text{boolean} \]

Parameters:

- \( expr1 \) and \( expr2 \) represent expressions

Description:

- The operator \( != \) evaluates to true iff its operands \( expr1 \) and \( expr2 \) are syntactically unequal and both different from error or constant expressions that are not constants and that evaluate to two different floating-point number with the global precision \( prec \). The user should be aware of the fact that because of floating-point evaluation, the operator \( != \) is not exactly the same as the negation of the mathematical equality.

  Note that the expressions \( (expr1 \neq expr2) \) and \( expr1 == expr2 \) do not evaluate to the same boolean value. See error for details.

Example 1:

```plaintext
> "Hello" != "Hello";
false
> "Hello" != "Salut";
true
> "Hello" != 5;
true
> 5 + x != 5 + x;
false
```

Example 2:

```plaintext
> 1 != exp(0);
false
> asin(1) * 2 != pi;
false
> exp(5) != log(4);
true
```

Example 3:

```plaintext
> sin(pi/6) != 1/2 * sqrt(3);
true
```

Example 4:

```plaintext
> prec = 12;
The precision has been set to 12 bits.
> 16384.1 != 16385.1;
false
```

Example 5:

```plaintext
> error != error;
false
```

See also: == (8.41), > (8.63), >= (8.62), <= (8.77), < (8.85), ! (8.93), && (8.6), || (8.97), error (8.44), prec (8.108)
8.92  **nop**

Name: **nop**
no operation

Usage:

```
 nop : void → void
```

Description:
- The command **nop** does nothing. This means it is an explicit parse element in the Sollya language that finally does not produce any result or side-effect.
- The keyword **nop** is implicit in some procedure definitions. Procedures without imperative body get parsed as if they had an imperative body containing one **nop** statement.

Example 1:

```
> nop;
```

Example 2:

```
> succ = proc(n) { return n + 1; };
> succ;
proc(n)
begin
 nop;
 return (n) + (1);
end
> succ(5);
6
```

See also: proc (8.116)

8.93  **not**

Name: **!**
boolean NOT operator

Usage:

```
! expr : boolean → boolean
```

Parameters:
- **expr** represents a boolean expression

Description:
- **!** evaluates to the boolean NOT of the boolean expression **expr**. **! expr** evaluates to true iff **expr** does not evaluate to true.

Example 1:

```
> ! false;
true
```

Example 2:

```
> !(1 == exp(0));
false
```

See also: && (8.6), || (8.97)
8.94 numerator

Name: numerator
gives the numerator of an expression

Usage:

\[
\text{numerator}(\text{expr}) : \text{function} \rightarrow \text{function}
\]

Parameters:

- \( \text{expr} \) represents an expression

Description:

- If \( \text{expr} \) represents a fraction \( \text{expr}_1 / \text{expr}_2 \), \text{numerator}(\text{expr}) \) returns the numerator of this fraction, i.e. \( \text{expr}_1 \).

  If \( \text{expr} \) represents something else, \text{numerator}(\text{expr}) \) returns the expression itself, i.e. \( \text{expr} \).

  Note that for all expressions \( \text{expr} \), \text{numerator}(\text{expr}) / \text{denominator}(\text{expr}) \) is equal to \( \text{expr} \).

Example 1:

> numerator(5/3);
5

Example 2:

> numerator(exp(x));
exp(x)

Example 3:

> a = 5/3;
> b = numerator(a)/denominator(a);
> print(a);
5 / 3
> print(b);
5 / 3

Example 4:

> a = exp(x/3);
> b = numerator(a)/denominator(a);
> print(a);
exp(x / 3)
> print(b);
exp(x / 3)

See also: denominator (8.29)

8.95 off

Name: off

special value for certain global variables.

Description:

- off is a special value used to deactivate certain functionalities of Sollya (namely canonical, timing, fullparentheses, midpointmode).
• As any value it can be affected to a variable and stored in lists.

Example 1:

```plaintext
> canonical=on;
Canonical automatic printing output has been activated.
> p=1+x+x^2;
> mode=off;
> p;
1 + x + x^2
> canonical=mode;
Canonical automatic printing output has been deactivated.
> p;
1 + x * (1 + x)
```

See also: on 8.96, canonical 8.18, timing 8.153, fullparentheses 8.60, midpointmode 8.88

8.96 on

Name: on
special value for certain global variables.

Description:

• **on** is a special value used to activate certain functionalities of Sollya (namely canonical, timing, fullparentheses, midpointmode).

• As any value it can be affected to a variable and stored in lists.

Example 1:

```plaintext
> p=1+x+x^2;
> mode=on;
> p;
1 + x * (1 + x)
> canonical=mode;
Canonical automatic printing output has been activated.
> p;
1 + x + x^2
```

See also: off 8.95, canonical 8.18, timing 8.153, fullparentheses 8.60, midpointmode 8.88

8.97 or

Name: ||
boolean OR operator

Usage:

```
epr1 || epr2 : (boolean, boolean) → boolean
```

Parameters:

• **epr1** and **epr2** represent boolean expressions

Description:

• || evaluates to the boolean OR of the two boolean expressions epr1 and epr2. || evaluates to true iff at least one of epr1 or epr2 evaluate to true.
Example 1:

```plaintext
> false || false;
false
```

Example 2:

```plaintext
> (1 == exp(0)) || (0 == log(1));
true
```

See also: && (8.6), ! (8.93)

### 8.98 parse

**Name:** parse  
**Parses an expression contained in a string**

**Usage:**

```plaintext
parse(string) : string → function | error
```

**Parameters:**

- `string` represents a character sequence

**Description:**

- `parse(string)` parses the character sequence `string` containing an expression built on constants and base functions.

  If the character sequence does not contain a well-defined expression, a warning is displayed indicating a syntax error and `parse` returns a `error` of type `error`.

Example 1:

```plaintext
> parse("exp(x));
exp(x)
```

Example 2:

```plaintext
> verbosity = 1!;
> parse("5 + * 3");
Warning: syntax error, unexpected MULTOKEN. Will try to continue parsing (expecting ";"). May leak memory.
Warning: the string "5 + * 3" could not be parsed by the miniparser.
Warning: at least one of the given expressions or a subexpression is not correctly typed or its evaluation has failed because of some error on a side-effect.
error
```

See also: execute (8.46), readfile (8.122)

### 8.99 perturb

**Name:** perturb  
**Indicates random perturbation of sampling points for externalplot**

**Usage:**

```plaintext
perturb : perturb
```
Description:

- The use of `perturb` in the command `externalplot` enables the addition of some random noise around each sampling point in `externalplot`.

See `externalplot` for details.

Example 1:

```bash
> bashexecute("gcc -fPIC -c externalplotexample.c");
> bashexecute("gcc -shared -o externalplotexample externalplotexample.o -lgmp -lmpfr");
> externalplot("./externalplotexample",relative,exp(x),[-1/2;1/2],12,perturb);
```

See also: `externalplot` [8.51], `absolute` [8.2], `relative` [8.124], `bashexecute` [8.15]

### 8.100 pi

Name: `pi`
the constant \( \pi \).

Description:

- `pi` is the constant \( \pi \), defined as half the period of sine and cosine.

- In Sollya, `pi` is considered as a 0-ary function. This way, the constant is not evaluated at the time of its definition but at the time of its use. For instance, when you define a constant or a function relating to \( \pi \), the current precision at the time of the definition does not matter. What is important is the current precision when you evaluate the function or the constant value.

- Remark that when you define an interval, the bounds are first evaluated and then the interval is defined. In this case, `pi` will be evaluated as any other constant value at the definition time of the interval, thus using the current precision at this time.

Example 1:

```bash
> verbosity=1!; prec=12!;
> a = 2*pi;
> a;
Warning: rounding has happened. The value displayed is a faithful rounding of the true result.
6.283
> prec=20!;
> a;
Warning: rounding has happened. The value displayed is a faithful rounding of the true result.
6.283187
```

Example 2:

```bash
> prec=12!;
> d = [pi; 5];
> d;
[3.1406;5]
> prec=20!;
> d;
[3.140625;5]
```

See also: `cos` [8.24], `sin` [8.140]
8.101 plot

Name: plot
plots one or several functions

Usage:

\[
\text{plot}(f_1, \ldots, f_n, I) : (\text{function, range}) \rightarrow \text{void}
\]
\[
\text{plot}(f_1, \ldots, f_n, I, \text{file, name}) : (\text{function, range, file, string}) \rightarrow \text{void}
\]
\[
\text{plot}(f_1, \ldots, f_n, I, \text{postscript, name}) : (\text{function, range, postscript, string}) \rightarrow \text{void}
\]
\[
\text{plot}(f_1, \ldots, f_n, I, \text{postscriptfile, name}) : (\text{function, range, postscriptfile, string}) \rightarrow \text{void}
\]
\[
\text{plot}(L, I) : (\text{list, range}) \rightarrow \text{void}
\]
\[
\text{plot}(L, I, \text{file, name}) : (\text{list, range, file, string}) \rightarrow \text{void}
\]
\[
\text{plot}(L, I, \text{postscript, name}) : (\text{list, range, postscript, string}) \rightarrow \text{void}
\]
\[
\text{plot}(L, I, \text{postscriptfile, name}) : (\text{list, range, postscriptfile, string}) \rightarrow \text{void}
\]

Parameters:

- \(f_1, \ldots, f_n\) are functions to be plotted.
- \(L\) is a list of functions to be plotted.
- \(I\) is the interval where the functions have to be plotted.
- \(\text{name}\) is a string representing the name of a file.

Description:

- This command plots one or several functions \(f_1, \ldots, f_n\) on an interval \(I\). Functions can be either given as parameters of \text{plot} or as a list \(L\) which elements are functions. Functions are plotted on the same graphic with different colors.
- If \(L\) contains an element that is not a function (or a constant), an error occurs.
- \text{plot} relies on the value of global variable \text{points}. Let \(n\) be the value of this variable. The algorithm is the following: each function is evaluated at \(n\) evenly distributed points in \(I\). At each point, the computed value is a faithful rounding of the exact value with a sufficiently big precision. Each point is finally plotted. This avoid numerical artefacts such as critical cancellations.
- You can save the graphic either as a data file or as a postscript file.
- If you use argument \text{file} with a string \text{name}, \text{Sollya} will save a data file called \text{name.dat} and a gnuplot directives file called \text{name.p}. Invoking gnuplot on \text{name.p} will plots datas stored in \text{name.dat}.
- If you use argument \text{postscript} with a string \text{name}, \text{Sollya} will save a postscript file called \text{name.eps} representing your graphic.
- If you use argument \text{postscriptfile} with a string \text{name}, \text{Sollya} will produce the corresponding \text{name.dat}, \text{name.p} and \text{name.eps}.
- This command uses gnuplot to produce the final graphic. If your terminal is not graphic (typically if you use \text{Sollya} by ssh without -X) gnuplot should be able to detect it and produce an ASCII-art version on the standard output. If it is not the case, you can either store the graphic in a postscript file to view it locally, or use \text{asciiplot} command.
- If every function is constant, \text{plot} will not plot them but just display their value.
- If the interval is reduced to a single point, \text{plot} will just display the value of the functions at this point.

Example 1:
> plot(sin(x),0,cos(x),[-Pi,Pi]);

Example 2:

> plot(sin(x),0,cos(x),[-Pi,Pi],postscriptfile,"plotSinCos");

Example 3:

> plot(exp(0), sin(1), [0;1]);
1
0.84147098480789650665250232163029899962256306079837

Example 4:

> plot(sin(x), cos(x), [1;1]);
0.84147098480789650665250232163029899962256306079837
0.54030230586813971744297660373231042061792

See also: externalplot [8.51], asciplot [8.9], file [8.54], postscript [8.104], postscriptfile [8.105], points [8.103]

8.102 plus

Name: +
addition function

Usage:

\[ function1 + function2 : (function, function) \rightarrow function \]

Parameters:

- \( function1 \) and \( function2 \) represent functions

Description:

- + represents the addition (function) on reals. The expression \( function1 + function2 \) stands for the function composed of the addition function and the two functions \( function1 \) and \( function2 \).

Example 1:

> 1 + 2;
3

Example 2:

> x + 2;
2 + x

Example 3:

> x + x;
x * 2

Example 4:

> diff(sin(x) + exp(x));
cos(x) + exp(x)

See also: − [8.89], * [8.90], / [8.36], ^ [8.106]
8.103 points

Name: **points**

controls the number of points chosen by **Sollya** in certain commands.

Description:

- **points** is a global variable. Its value represents the number of points used in numerical algorithms of **Sollya** (namely **dirtyinfnorm**, **dirtyintegral**, **dirtyfindzeros**, **plot**).

Example 1:

```plaintext
> f=x^2*sin(1/x);
> points=10;
The number of points has been set to 10.
> dirtyfindzeros(f, [0;1]);
[[0, 0.318309886183790671537767526745028724068919291480918]]
> points=100;
The number of points has been set to 100.
> dirtyfindzeros(f, [0;1]);
[[0, 2.448537586029159018289809749617594159147637806224e-2, 3.506776513153229968375297261938920804652[...]]
```

See also: **dirtyinfnorm** (8.33), **dirtyintegral** (8.34), **dirtyfindzeros** (8.32), **plot** (8.101)

8.104 postscript

Name: **postscript**

special value for commands **plot** and **externalplot**

Description:

- **postscript** is a special value used in commands **plot** and **externalplot** to save the result of the command in a postscript file.

  - As any value it can be affected to a variable and stored in lists.

Example 1:

```plaintext
> savemode=postscript;
> name="plotSinCos";
> plot(sin(x),0,cos(x),[-Pi,Pi],savemode, name);
```

See also: **externalplot** (8.51), **plot** (8.101), **file** (8.54), **postscriptfile** (8.105)

8.105 postscriptfile

Name: **postscriptfile**

special value for commands **plot** and **externalplot**

Description:

- **postscriptfile** is a special value used in commands **plot** and **externalplot** to save the result of the command in a data file and a postscript file.
• As any value it can be affected to a variable and stored in lists.

Example 1:

```plaintext
> savemode=postscriptfile;
> name="plotSinCos";
> plot(sin(x),0,cos(x),[-Pi,pi],savemode, name);
```

See also: externalplot (8.51), plot (8.101), file (8.54), postscript (8.104)

8.106 power

Name: ^

power function

Usage:

```
function1 ^ function2 : (function, function) → function
```

Parameters:

• function1 and function2 represent functions

Description:

• ^ represents the power (function) on reals. The expression function1 ^ function2 stands for the function composed of the power function and the two functions function1 and function2, where function1 is the base and function2 the exponent. If function2 is a constant integer, ^ is defined on negative values of function1. Otherwise ^ is defined as e^{y \log x}.

• Note that whenever several ^ are composed, the priority goes to the last ^. This corresponds to the natural way of thinking when a tower of powers is written on a paper. Thus, 2^3^5 is read as 2^{3^5} and is interpreted as 2^{(3^5)}.

Example 1:

```plaintext
> 5 ^ 2;
25
```

Example 2:

```plaintext
> x ^ 2;
x^2
```

Example 3:

```plaintext
> 3 ^ (-5);
4.1152263374485596707818930041152263374485596707818e-3
```

Example 4:

```plaintext
> (-3) ^ (-2.5);
@NaN@  
```

Example 5:

```plaintext
> diff(sin(x) ^ exp(x));

\( \sin(x)^{\exp(x)} \* ((\cos(x) \* \exp(x)) / \sin(x) + \exp(x) \* \log(\sin(x))) \)
```

Example 6:
\begin{verbatim}
> 2^3^5;
1.4134776518227074636666380005943348126619871175005e73
> (2^3)^5;
32768
> 2^(3^5);
1.4134776518227074636666380005943348126619871175005e73
\end{verbatim}

See also: + (8.102), − (8.89), ∗ (8.90), / (8.36)

8.107 powers
Name: powers
special value for global state display

Description:

- **powers** is a special value used for the global state display. If the global state display is equal to **powers**, all data will be output in dyadic notation with numbers displayed in a Maple and PARI/GP compatible format.

  As any value it can be affected to a variable and stored in lists.

See also: decimal (8.26), dyadic (8.40), hexadecimal (8.66), binary (8.16)

8.108 prec
Name: prec
controls the precision used in numerical computations.

Description:

- **prec** is a global variable. Its value represents the precision of the floating-point format used in numerical computations.

  - Many commands try to adapt their intern precision in order to have approximately \( n \) correct bits in output, where \( n \) is the value of **prec**.

Example 1:

\begin{verbatim}
> display=binary!;
> prec=50;
The precision has been set to 50 bits.
> dirtyinfnorm(exp(x),[1;2]);
1.110110011100101101111001010111001010011011110110111_2 * 2^(2)
> prec=100;
The precision has been set to 100 bits.
> dirtyinfnorm(exp(x),[1;2]);
1.1101100111001011011110010101110010100110111101101111010011001110
111010001000000111111_2 * 2^(-2)
\end{verbatim}

8.109 precision
Name: precision
returns the precision necessary to represent a number.

Usage:

\[
\text{precision}(x) : \text{constant} \rightarrow \text{integer}
\]
Parameters:

- $x$ is a dyadic number.

Description:

- **precision**\( (x) \) is by definition $|x|$ if $x$ equals 0, NaN, or Inf.
- If $x$ is not zero, it can be uniquely written as $x = m \cdot 2^e$ where $m$ is an odd integer and $e$ is an integer. **precision**\( (x) \) returns the number of bits necessary to write $m$ (e.g. $\lceil \log_2(m) \rceil$).

Example 1:

```
> a=round(Pi,20,RN);
> precision(a);
19
> m=mantissa(a);
> ceil(log2(m));
19
```

See also: **mantissa** [8.86], **exponent** [8.50]

8.110 **prepend**

**Name:** .:

add an element at the beginning of a list.

**Usage:**

\[
x .: L : (\text{any type, list}) \rightarrow \text{list}
\]

**Parameters:**

- $x$ is an object of any type.
- $L$ is a list (possibly empty).

**Description:**

- .: adds the element $x$ at the beginning of the list $L$.
- Note that since $x$ may be of any type, it can be in particular a list.

Example 1:

```
> 1.:[[2,3,4]];
[[1, 2, 3, 4]]
```

Example 2:

```
> [[1,2,3]].:[[4,5,6]];
[[[1, 2, 3]], 4, 5, 6]
```

Example 3:

```
> 1.:[[]];
[[1]]
```

See also: .: [8.7], @ [8.22]
8.111 print

Name: print
prints an expression

Usage:

\begin{align*}
\text{print}(expr\,\ldots,\,exprn) & : \text{(any type,\ldots, any type)} \Rightarrow \text{void} \\
\text{print}(expr\,\ldots,\,exprn) & > \text{filename} : \text{(any type,\ldots, any type, string)} \Rightarrow \text{void} \\
\text{print}(expr\,\ldots,\,exprn) & >> \text{filename} : \text{(any type,\ldots,any type, string)} \Rightarrow \text{void}
\end{align*}

Parameters:

- \textit{expr} represents an expression
- \textit{filename} represents a character sequence indicating a file name

Description:

- \texttt{print}(\texttt{expr}1,\ldots,\texttt{exprn}) prints the expressions \texttt{expr}1 through \texttt{exprn} separated by spaces and followed by a newline.

  If a second argument \texttt{filename} is given after a single ">", the displaying is not output on the standard output of \texttt{Sollya} but if in the file \texttt{filename} that get newly created or overwritten. If a double ">>" is given, the output will be appended to the file \texttt{filename}.

  The global variables display, midpointmode and fullparentheses have some influence on the formatting of the output (see display, midpointmode and fullparentheses).

  Remark that if one of the expressions \texttt{expri} given in argument is of type string, the character sequence \texttt{expri} evaluates to is displayed. However, if \texttt{expri} is of type list and this list contains a variable of type string, the expression for the list is displayed, i.e. all character sequences get displayed surrounded by quotes ("""). Nevertheless, escape sequences used upon defining character sequences are interpreted immediately.

Example 1:

\begin{verbatim}
> print(x + 2 + exp(sin(x)));  
  x + 2 + exp(sin(x))  
> print("Hello","world");  
  Hello world  
> print("Hello","you", 4 + 3, "other persons.");  
  Hello you 7 other persons.
\end{verbatim}

Example 2:

\begin{verbatim}
> print("Hello");  
  Hello  
> print(["Hello"])  
  [["Hello"]  
> s = "Hello";  
> print(s,[s]);  
  Hello [["Hello"]
> t = "Hello\tyou";  
> print(t,[t]);  
  Hello you [["Hello you"]
\end{verbatim}

Example 3:

\begin{verbatim}
> print(x + 2 + exp(sin(x))) > "foo.sol";  
> readfile("foo.sol");  
  x + 2 + exp(sin(x))
\end{verbatim}
Example 4:

```plaintext
> print(x + 2 + exp(sin(x))) >> "foo.sol";
```

Example 5:
> display = decimal;
Display mode is decimal numbers.
> a = evaluate(sin(pi * x), 0.25);
> b = evaluate(sin(pi * x), [0.25; 0.25 + 1b-50]);
> print(a);
0.7071067811865475244008436210484903928483593768847
> display = binary;
Display mode is binary numbers.
> print(a);
1.011010100000101111111111111101001000001010111011111110110011010101000001010011001111011111101110101010100001000001110111010100010111010100010110001011001
> display = hexadecimal;
Display mode is hexadecimal numbers.
> print(a);
0xb.504f333f9de6484597d89b3754abe9f1d6f60ba88p-4
> display = dyadic;
Display mode is dyadic numbers.
> print(a);
330700069911015586133239834888220944360067107133265b-165
> display = powers;
Display mode is dyadic numbers in integer-power-of-2 notation.
> print(a);
330700069911015586133239834888220944360067107133265 * 2^-165
> display = decimal;
Display mode is decimal numbers.
> midpointmode = off;
Midpoint mode has been deactivated.
> print(b);
[0.7071067811865475244008436210484903928483593768844;0.7071067811865494974372178251755747782646274417048]
> midpointmode = on;
Midpoint mode has been activated.
> print(b);
[0.7071067811865475244008436210484903928483593768844;0.7071067811865494974372178251755747782646274417048]
> display = dyadic;
Display mode is dyadic numbers.
> print(b);
[206687543694384741333274968013809022504194195829b-161;1653500349555082544419623701938593641432675156571b-164]
> display = decimal;
Display mode is decimal numbers.
> autosimplify = off;
Automatic pure tree simplification has been deactivated.
> fullparentheses = off;
Full parentheses mode has been deactivated.
> print(x + x * ((x + 1) + 1));
x + x * (x + 1 + 1)
> fullparentheses = on;
Full parentheses mode has been activated.
> print(x + x * ((x + 1) + 1));
x + (x * ((x + 1) + 1))
8.112 printexpansion

Name: printexpansion

prints a polynomial in Horner form with its coefficients written as a expansions of double precision numbers

Usage:

\texttt{printexpansion}(\texttt{polynomial}) : (function) \to void

Parameters:

\begin{itemize}
  \item \texttt{polynomial} represents the polynomial to be printed
\end{itemize}

Description:

\begin{itemize}
  \item The command \texttt{printexpansion} prints the polynomial \texttt{polynomial} in Horner form writing its coefficients as expansions of double precision numbers. The double precision numbers themselves are displayed in hexadecimal memory notation (see \texttt{printhexa}).

  If some of the coefficients of the polynomial \texttt{polynomial} are not floating-point constants but constant expressions, they are evaluated to floating-point constants using the global precision \texttt{prec}. If a rounding occurs in this evaluation, a warning is displayed.

  If the exponent range of double precision is not sufficient to display all the mantissa bits of a coefficient, the coefficient is displayed rounded and a warning is displayed.

  If the argument \texttt{polynomial} does not a polynomial, nothing but a warning or a newline is displayed.

  Constants can be displayed using \texttt{printexpansion} since they are polynomials of degree 0.
\end{itemize}

Example 1:

\begin{verbatim}
> printexpansion(roundcoefficients(taylor(exp(x),5,0),[|DD...|]));
0x3ff0000000000000 + x * (0x3ff0000000000000 + x * (0x3fe0000000000000 + x * ((0x3fc5555555555555 + 0x3c65555555555555) + x * ((0x3fa5555555555555 + 0x3c45555555555555) + x * (0x3f81111111111111 + 0x3c01111111111111)))))
\end{verbatim}

Example 2:

\begin{verbatim}
> printexpansion(remez(exp(x),5,[-1;1]));
(0x3ff0002ee908ce9 + 0xbc7d9f9eb225af5 + 0xb8d5834b08b1f18) + x * ((0x3ff0002835917719 + 0x3c682c073b25ef + 0xb902cf62b54b77b) + x * ((0x3fdff2d7e6a9c5e9 + 0x3bc7b09a55b0d520f + 0xb915b639add55731 + 0x35b0000000000000) + x * ((0x3fc54d6738ba09f + 0x3c4867596a0631cf + 0xb8e0f7566d4af62 + 0x3580000000000000) + x * ((0x3fa66c209b825167 + 0x3c45ec5b6655b076 + 0xb8d8c125286400ba + 0x3570000000000000) + x * (0x3f81e55425e72ab4 + 0x3c263b25a1bf597b + 0xb8c434e0401dadea + 0x3570000000000000))))
\end{verbatim}

Example 3:

\begin{verbatim}
> verbosity = 1!;
> prec = 3500!;
> printexpansion(pi);
((0x400921fb54442d18 + 0x3ca1a62633145c07 + 0xb92f1976b7ed8fbc + 0x35c4cf98e80417)
7d + 0x32631d9c9128a5 + 0x2e6cf3c6809b0df + 0x2b5193cd3a431b + 0x27e8158536f928a + 0x26e7b9f9abdb6ea9 + 0xa0e6dd0db2544cf + 0xd779fb1bd1310ba + 0x1a1a6376d60bbff6 + 0x99aa485fa40908e + 0x9335e0129598169 + 0x8fd60db6ee3b4e0 + 0xc959b6799a8131c + 0x08f6c70801f2e28 + 0x05963bc0598a483 + 0x023871574e69a459 + 0x800000000005702d3 + 0x8000000000000000)
Warning: the expansion is not complete because of the limited exponent range of double precision.
Warning: rounding occurred while printing.
\end{verbatim}

See also: \texttt{printhexa}, \texttt{horner}, \texttt{print}, \texttt{prec}, \texttt{remez}, \texttt{taylor}, \texttt{roundcoefficients}.
8.113 printfloat

Name: printfloat
prints a constant value as a hexadecimal single precision number

Usage:

    printfloat(constant) : constant → void

Parameters:

- constant represents a constant

Description:

- Prints a constant value as a hexadecimal number on 8 hexadecimal digits. The hexadecimal number represents the integer equivalent to the 32 bit memory representation of the constant considered as a single precision number.

  If the constant value does not hold on a single precision number, it is first rounded to the nearest single precision number before displayed. A warning is displayed in this case.

Example 1:

    > printfloat(3);
    0x40400000

Example 2:

    > prec=100!
    > verbosity = 1!
    > printfloat(exp(5));
    Warning: the given expression is not a constant but an expression to evaluate.
    Warning: rounding occurred before printing a value as a simple.
    0x431469c5

See also: printhexa (8.114)

8.114 printhexa

Name: printhexa
prints a constant value as a hexadecimal double precision number

Usage:

    printhexa(constant) : constant → void

Parameters:

- constant represents a constant

Description:

- Prints a constant value as a hexadecimal number on 16 hexadecimal digits. The hexadecimal number represents the integer equivalent to the 64 bit memory representation of the constant considered as a double precision number.

  If the constant value does not hold on a double precision number, it is first rounded to the nearest double precision number before displayed. A warning is displayed in this case.

Example 1:
Example 2:

```
> prec=100!;
> verbosity = 1!;
> printhexa(exp(5));
Warning: the given expression is not a constant but an expression to evaluate.
Warning: rounding occurred before printing a value as a double.
0x40628d389970338f
```

See also: `printfloat` [8.113], `printexpansion` [8.112]

### 8.115 `printxml`

**Name:** `printxml`  
prints an expression as an MathML-Content-Tree

**Usage:**

```
printxml(expr) : function → void
printxml(expr) > filename : (function, string) → void
printxml(expr) >> filename : (function, string) → void
```

**Parameters:**

- `expr` represents a functional expression
- `filename` represents a character sequence indicating a file name

**Description:**

- `printxml(expr)` prints the functional expression `expr` as a tree of MathML Content Definition Markups. This XML tree can be re-read in external tools or by usage of the `readxml` command.
- If a second argument `filename` is given after a single `>`, the MathML tree is not output on the standard output of Sollya but if in the file `filename` that get newly created or overwritten. If a double `>>` is given, the output will be appended to the file `filename`.

**Example 1:**
> printxml(x + 2 + exp(sin(x)));

<?xml version="1.0" encoding="UTF-8"?>
<!-- generated by sollya: http://sollya.gforge.inria.fr/ -->
<!-- syntax: printxml(...); example: printxml(x^2-2*x+5); -->
<?xml-stylesheet type="text/xsl" href="mathmlc2p-web.xsl"?>
<!-- This stylesheet allows direct web browsing of MathML-c XML files (http://o r file://) -->

<math xmlns="http://www.w3.org/1998/Math/MathML">
  <semantics>
    <annotation-xml encoding="MathML-Content">
      <lambda>
        <bvar><ci> x </ci></bvar>

      </lambda>
    </annotation-xml>
    <annotation encoding="sollya/text">(x + 1b1) + exp(sin(x))</annotation>
  </semantics>
</math>

Example 2:

> printxml(x + 2 + exp(sin(x))) > "foo.xml";

Example 3:

> printxml(x + 2 + exp(sin(x))) >> "foo.xml";

See also: readxml [8.123], print [8.111], write [8.160]

8.116 proc

Name: proc

defines a Sollya procedure

Usage:
**proc**(*formal parameter*$_1$, *formal parameter*$_2$, ..., *formal parameter*$_n$) **begin** procedure body **end**: void

**proc**(*formal parameter*$_1$, *formal parameter*$_2$, ..., *formal parameter*$_n$) **begin** procedure body **return**

expression; **end**: any type → procedure

Parameters:

- *formal parameter*$_1$, *formal parameter*$_2$ through *formal parameter*$_n$ represent identifiers used as formal parameters
- **procedure body** represents the imperative statements in the body of the procedure
- **expression** represents the expression **proc** shall evaluate to

Description:

- The **proc** keyword allows for defining procedures in the **Sollya** language. These procedures are common **Sollya** objects that can be applied to actual parameters after definition. Upon such an application, the **Sollya** interpreter applies the actual parameters to the formal parameters *formal parameter*$_1$ through *formal parameter*$_n$ and executes the **procedure body**. The procedure applied to actual parameters evaluates then to the expression **expression** in the **return** statement after the **procedure body** or to **void**, if no return statement is given (i.e. a **return void** statement is implicitly given).

- **Sollya** procedures defined by **proc** have no name. They can be bound to an identifier by assigning the procedure object a **proc** expression produces to an identifier. However, it is possible to use procedures without giving them any name. For instance, **Sollya** procedures, i.e. procedure objects, can be elements of lists. They can even be given as an argument to other internal **Sollya** procedures. See also **procedure** on this subject.

- Upon definition of a **Sollya** procedure using **proc**, no type check is performed. More precisely, the statements in **procedure body** are merely parsed but not interpreted upon procedure definition with **proc**. Type checks are performed once the procedure is applied to actual parameters or to **void**. At this time, it is checked whether the number of actual parameters corresponds to the number of formal parameters. Type checks are further performed upon execution of each statement in **procedure body** and upon evaluation of the expression **expression** to be returned.

Procedures defined by **proc** containing a **quit** or **restart** command cannot be executed (i.e. applied). Upon application of a procedure, the **Sollya** interpreter checks beforehand for such a statement. If one is found, the application of the procedure to its arguments evaluates to **error**. A warning is displayed. Remark that in contrast to other type or semantic correctness checks, this check is really performed before interpreting any other statement in body of the procedure.

- By means provided by the **var** keyword, it is possible to declare local variables and thus to have full support of recursive procedures. This means a procedure defined using **proc** may contain in its **procedure body** an application of itself to some actual parameters: it suffices to assign the procedure (object) to an identifier with an appropriate name.

- **Sollya** procedures defined using **proc** may return other procedures. Further **procedure body** may contain assignments of locally defined procedure objects to identifiers. See **var** for the particular behaviour of local and global variables.

- The expression **expression** returned by a procedure is evaluated with regard to **Sollya** commands, procedures and external procedures. Simplification may be performed. However, an application of a procedure defined by **proc** to actual parameters evaluates to the expression **expression** that may contain the free global variable or that may be composed.

Example 1:
Example 2:

```plaintext
> add = proc(m,n) { var res; res := m + n; return res; };  
> add(5,6);  
11  
> add;  
proc(m, n)  
begin  
var res;  
res := (m) + (n);  
return res;  
end  
> verbosity = 1!;  
> add(3);  
Warning: at least one of the given expressions or a subexpression is not correctly typed  
or its evaluation has failed because of some error on a side-effect.  
error  
> add(true,false);  
Warning: at least one of the given expressions or a subexpression is not correctly typed  
or its evaluation has failed because of some error on a side-effect.  
Warning: the given expression or command could not be handled.  
Warning: the given expression or command could not be handled.  
error
```

Example 3:

```plaintext
> succ = proc(n) { return n + 1; };  
> succ(5);  
6  
> 3 + succ(0);  
4  
> succ;  
proc(n)  
begin  
nop;  
return (n) + (1);  
end
```

Example 4:

```plaintext
> succ = proc(n) { return n + 1; };  
> succ(5);  
6  
> succ(x);  
1 + x
```
Example 5:

```plaintext
> fac = proc(n) { var res; if (n == 0) then res := 1 else res := n * fac(n - 1); return res; }; > fac(5); 120 > fac(11); 39916800 > fac; proc(n) begin var res; if (n) == (0) then res := 1 else res := (n) * (fac((n) - (1))); return res; end
```

Example 6:

```plaintext
> myprocs = [| proc(m,n) { return m + n; }, proc(m,n) { return m - n; } |]; > (myprocs[0])(5,6); 11 > (myprocs[1])(5,6); -1 > succ = proc(n) { return n + 1; }; > pred = proc(n) { return n - 1; }; > applier = proc(p,n) { return p(n); }; > applier(succ,5); 6 > applier(pred,5); 4
```

Example 7:
> verbosity = 1!
> myquit = proc(n) { print(n); quit; }
> myquit;
proc(n)
begin
print(n);
quit;
return void;
end
> myquit(5);
Warning: a quit or restart command may not be part of a procedure body. The procedure will not be executed.
Warning: an error occurred while executing a procedure. Warning: the given expression or command could not be handled.
error

Example 8:

> printsucc = proc(n) { var succ; succ = proc(n) { return n + 1; }; print("Successor of ",n," is ",succ(n)); }
> printsucc(5);
Successor of 5 is 6

Example 9:

> makeadd = proc(n) { var add; print("n =",n); add = proc(m,n) { return n + m; } ; return add; }
> makeadd(4);
n = 4
proc(m, n)
begin
nop;
return (n) + (m);
end
> (makeadd(4))(5,6);
n = 4
11

See also: return (8.128), externalproc (8.52), void (8.158), quit (8.118), restart (8.127), var (8.156)

8.117 procedure

Name: procedure

defines and assigns a Sollya procedure

Usage:

procedure identifier(formal parameter1, formal parameter2,..., formal parameter n) begin procedure
body end : void → void

procedure identifier(formal parameter1, formal parameter2,..., formal parameter n) begin procedure
body return expression; end : any type → void

Parameters:

- identifier represents the name of the procedure to be defined and assigned
- formal parameter1, formal parameter2 through formal parameter n represent identifiers used as formal parameters
- **procedure body** represents the imperative statements in the body of the procedure
- **expression** represents the expression **procedure** shall evaluate to

**Description:**
- The **procedure** keyword allows for defining and assigning procedures in the Sollya language. It is an abbreviation to a procedure definition using **proc** with the same formal parameters, procedure body and return-expression followed by an assignment of the procedure (object) to the identifier **identifier**. In particular, all rules concerning local variables declared using the **var** keyword apply for **procedure**.

**Example 1:**

```plaintext
> procedure succ(n) { return n + 1; }
> succ(5);
6
> 3 + succ(0);
4
> succ;
proc(n)
begin
nop;
return (n) + (1);
end
```

See also: **proc** [8.116], **var** [8.156]

**8.118 quit**

**Name:** quit

quits Sollya

**Usage:**

```plaintext
quit : void → void
```

**Description:**
- The command **quit**, when executed abandons the execution of a Sollya script and leaves the Sollya interpreter unless the **quit** command is executed in a Sollya script read into a main Sollya script by **execute** or **#include**.

Upon exiting the Sollya interpreter, all state is thrown away, all memory is deallocated, all bound libraries are unbound and the temporary files produced by **plot** and **externalplot** are deleted.

If the **quit** command does not lead to the abandon of the Sollya interpreter, a warning is displayed.

**Example 1:**

```plaintext
> quit;
```

See also: **restart** [8.127], **execute** [8.46], **plot** [8.101], **externalplot** [8.51]

**8.119 range**

**Name:** range

keyword representing a range type

**Usage:**
range : type type

Description:

- **range** represents the range type for declarations of external procedures by means of **externalproc**.
  
  Remark that in contrast to other indicators, type indicators like **range** cannot be handled outside the **externalproc** context. In particular, they cannot be assigned to variables.

See also: externalproc (8.52), boolean (8.17), constant (8.23), function (8.61), integer (8.73), list of (8.80), string (8.144)

8.120 rationalapprox

Name: rationalapprox

returns a fraction close to a given number.

Usage:

\[ \text{rationalapprox}(x,n) : (\text{constant}, \text{integer}) \rightarrow \text{function} \]

Parameters:

- \( x \) is a number to approximate.
- \( n \) is an integer (representing a format).

Description:

- **rationalapprox**(\( x,n \)) returns a constant function of the form \( a/b \) where \( a \) and \( b \) are integers. The value \( a/b \) is an approximation of \( x \). The quality of this approximation is determined by the parameter \( n \) that indicates the number of correct bits that \( a/b \) should have.

- The command is not safe in the sense that it is not ensured that the error between \( a/b \) and \( x \) is less than \( 2^{-n} \).

- The following algorithm is used: \( x \) is first rounded downwards and upwards to a format of \( n \) bits, thus obtaining an interval \([x_l, x_u]\). This interval is then developed into a continued fraction as far as the representation is the same for every elements of \([x_l, x_u]\). The corresponding fraction is returned.

- Since rational numbers are not a primitive object of Sollya, the fraction is returned as a constant function. It can be quite amazing, because Sollya immediately simplifies a constant function by evaluating it when the constant has to be displayed. To avoid this, you can use **print** (that displays the expression representing the constant and not the constant itself) or the commands **numerator** and **denominator**.

Example 1:

```
> pi10 = rationalapprox(Pi,10);
> pi50 = rationalapprox(Pi,50);
> pi100 = rationalapprox(Pi,100);
> print(pi10, " : ", simplify(floor(-log2(abs(pi10-Pi)/Pi))), "bits." );
22 / 7 : 11 bits.
> print(pi50, " : ", simplify(floor(-log2(abs(pi50-Pi)/Pi))), "bits." );
90982559 / 28960648 : 50 bits.
> print(pi100, " : ", simplify(floor(-log2(abs(pi100-Pi)/Pi))), "bits." );
4850225745369133 / 1543874804974140 : 101 bits.
```

Example 2:
\begin{verbatim}
> a=0.1;
> b=rationalapprox(a,4);
> numerator(b); denominator(b);
1
10
> print(simplify(floor(-log2(abs((b-a)/a)))), "bits.");
166 bits.
\end{verbatim}

See also: \texttt{print} \texttt{(8.111)}, \texttt{numerator} \texttt{(8.91)}, \texttt{denominator} \texttt{(8.29)}

\section*{8.121 rd}

Name: \texttt{RD}

current constant representing rounding-downwards mode.

Description:

\begin{itemize}
\item \texttt{RD} is used in command \texttt{round} to specify that the value \( x \) must be rounded to the greatest floating-point number \( y \) such that \( y \leq x \).
\end{itemize}

Example 1:

\begin{verbatim}
> display=binary!;
> round(Pi,20,RD);
1.1001001000011111101_2 * 2^(1)
\end{verbatim}

See also: \texttt{RZ} \texttt{(8.136)}, \texttt{RU} \texttt{(8.135)}, \texttt{RN} \texttt{(8.130)}, \texttt{round} \texttt{(8.131)}

\section*{8.122 readfile}

Name: \texttt{readfile}

reads the content of a file into a string variable

Usage:

\begin{verbatim}
readfile(filename) : string → string
\end{verbatim}

Parameters:

\begin{itemize}
\item \texttt{filename} represents a character sequence indicating a file name
\end{itemize}

Description:

\begin{itemize}
\item \texttt{readfile} opens the file indicated by \texttt{filename}, reads it and puts its contents in a character sequence of type \texttt{string} that is returned.

If the file indicated by \texttt{filename} cannot be opened for reading, a warning is displayed and \texttt{readfile} evaluates to an \texttt{error} variable of type \texttt{error}.
\end{itemize}

Example 1:

\begin{verbatim}
> print("Hello world") > "myfile.txt";
> t = readfile("myfile.txt");
> t;
Hello world
\end{verbatim}

Example 2:
> verbosity=1!
> readfile("afile.txt");
Warning: the file "afile.txt" could not be opened for reading.
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error

See also: parse (8.98), execute (8.46), write (8.160), print (8.111)

8.123 readxml

Name: readxml

reads an expression written as a MathML-Content-Tree in a file

Usage:

\[
\text{readxml}(\text{filename}) : \text{string} \rightarrow \text{function} \mid \text{error}
\]

Parameters:

- \text{filename} represents a character sequence indicating a file name

Description:

- \text{readxml}(\text{filename}) reads the first occurrence of a lambda application with one bounded variable on applications of the supported basic functions in file \text{filename} and returns it as a Sollya functional expression.

  If the file \text{filename} does not contain a valid MathML-Content tree, \text{readxml} tries to find an "annotation encoding" markup of type "sollya/text". If this annotation contains a character sequence that can be parsed by \text{parse}, \text{readxml} returns that expression. Otherwise \text{readxml} displays a warning and returns an error variable of type error.

Example 1:

\[
> \text{readxml("readxmlexample.xml")};
2 + x + \exp(\sin(x))
\]

See also: printxml (8.115), readfile (8.122), parse (8.98)

8.124 relative

Name: perturb

indicates a relative error for externalplot

Usage:

\[
\text{perturb} : \text{absolute} | \text{relative}
\]

Description:

- The use of \text{perturb} in the command \text{externalplot} indicates that during plotting in \text{externalplot} a relative error is to be considered.

  See externalplot for details.

Example 1:

\[
> \text{bashexec("gcc -fPIC -c externalplotexample.c")};
> \text{bashexec("gcc -shared -o externalplotexample externalplotexample.o -lgmp -lmpfr")};
> \text{externalplot("./externalplotexample","relative,exp(x),[-1/2;1/2],12,\text{perturb})};
\]

See also: externalplot (8.51), absolute (8.2), bashexec (8.15)
8.125 remez

Name: remez
computes the minimax of a function on an interval.

Usage:

\[
\text{remez}(f, n, \text{range}, w, \text{quality}) : (\text{function}, \text{integer}, \text{range}, \text{function}, \text{constant}) \rightarrow \text{function}
\]

\[
\text{remez}(f, L, \text{range}, w, \text{quality}) : (\text{function}, \text{list}, \text{range}, \text{function}, \text{constant}) \rightarrow \text{function}
\]

Parameters:

- \( f \) is the function to be approximated
- \( n \) is the degree of the polynomial that must approximate \( f \)
- \( L \) is a list of monomials that can be used to represent the polynomial that must approximate \( f \)
- \( \text{range} \) is the interval where the function must be approximated
- \( w \) (optional) is a weight function. Default is 1.
- \( \text{quality} \) (optional) is a parameter that controls the quality of the returned polynomial \( p \), with respect to the exact minimax \( p^* \). Default is \( 1 \times 10^{-5} \).

Description:

- \text{remez} computes an approximation of the function \( f \) with respect to the weight function \( w \) on the interval \( \text{range} \). More precisely, it searches a polynomial \( p \) such that \( \|pw - f\|_\infty \) is (almost minimal) among all polynomials \( p \) of a certain form. The norm is the infinite norm, e.g. \( \|g\|_\infty = \max\{|g(x)|, x \in \text{range}\} \).
- If \( w = 1 \) (the default case), it consists in searching the best polynomial approximation of \( f \) with respect to the absolute error. If \( f = 1 \) and \( w \) is of the form \( 1/g \), it consists in searching the best polynomial approximation of \( g \) with respect to the relative error.
- If \( n \) is given, the polynomial \( p \) is searched among the polynomials with degree not greater than \( n \). If \( L \) is given, the polynomial \( p \) is searched as a linear combination of monomials \( X^k \) where \( k \) belongs to \( L \). \( L \) may contain ellipses but cannot be ellip tic.
- The polynomial is obtained by a convergent iteration called Remez’ algorithm. The algorithm computes a sequence \( p_1, \ldots, p_k, \ldots \) such that \( e_k = \|p_k w - f\|_\infty \) converges towards the optimal value \( e \). The algorithm is stopped when the relative error between \( e_k \) and \( e \) is less than \( \text{quality} \).
- Note: the algorithm may not converge in certain cases. Moreover, it may converge towards a polynomial that is not optimal. These cases correspond to the cases when the Haar condition is not fulfilled. See [Cheney - Approximation theory] for details.

Example 1:

\[
\begin{align*}
> & p = \text{remez}(\exp(x), 5, [0;1]); \\
> & \text{degree}(p); \\
> & 5 \\
> & \text{dirtyinfnorm}(p-\exp(x), [0;1]); \\
> & 1.1295698463821453649843017679626063762687503980789e-6
\end{align*}
\]

Example 2:

\[
\begin{align*}
> & p = \text{remez}(1, [10, 2, 4, 6, 8], [0, \text{Pi}/4], 1/\cos(x)); \\
> & \text{canonical}=\text{on}!; \\
> & p; \\
> & 0.99999999994393749280444571988532724907643631727379 + -0.499999957155746773720 \ 49316308368345636630397481628 + x^2 + 4.1666613233501090518825397221274871865177 \ 52418561e-2 + x^4 + -1.388652914752861417071806583317679962601690152622e-3 * x \ ^6 + 2.4372679191116269422173866792791676168996590663655e-5 * x^8
\end{align*}
\]
Example 3:

```plaintext
> p1 = remez(exp(x),5,[0;1],default,1e-5);
> p2 = remez(exp(x),5,[0;1],default,1e-10);
> p3 = remez(exp(x),5,[0;1],default,1e-15);
> dirtyinfnorm(p1-exp(x),[0;1]);
    1.12956984638214536843017679626063762687503980789e-6
> dirtyinfnorm(p2-exp(x),[0;1]);

> dirtyinfnorm(p3-exp(x),[0;1]);
    1.12956980227478687321742075177283886192666255395e-6
```

See also: dirtyinfnorm [8.33], infnorm [8.72]

### 8.126 rename

**Name:** rename

rename the free variable.

**Usage:**

```plaintext
rename(ident1,ident2) : void
```

**Parameters:**

- `ident1` is the current name of the free variable.
- `ident2` is a fresh name.

**Description:**

- `rename` lets one change the name of the free variable. *Sollya* can handle only one free variable at a time. The first time in a session that an unbound name is used in a context where it can be interpreted as a free variable, the name is used to represent the free variable of *Sollya*. In the following, this name can be changed using `rename`.
- Be careful: if `ident2` has been set before, its value will be lost. Use the command `isbound` to know if `ident2` is already used or not.
- If `ident1` is not the current name of the free variable, an error occurs.
- If `rename` is used at a time when the name of the free variable has not been defined, `ident1` is just ignored and the name of the free variable is set to `ident2`.

**Example 1:**

```plaintext
> f=sin(x);
> f;
sin(x)
> rename(x,y);
> f;
sin(y)
```

**Example 2:**

```plaintext
> a=1;
> f=sin(x);
> rename(x,a);
> a;
a
> f;
sin(a)
```
Example 3:

```plaintext
> verbosity=1!
> f=sin(x);
> rename(y,z);
Warning: the current free variable is named "x" and not "y". Can only rename the free variable.
The last command will have no effect.
```

Example 4:

```plaintext
> rename(x,y);
> isbound(x);
false
> isbound(y);
true
```

See also: `isbound` \[8.75\]

### 8.127 restart

**Name:** `restart`

brings Sollya back to its initial state

**Usage:**

```
restart : void → void
```

**Description:**

- The command `restart` brings Sollya back to its initial state. All current state is abandoned, all libraries unbound and all memory freed.

The `restart` command has no effect when executed inside a Sollya script read into a main Sollya script using `execute`. It is executed in a Sollya script included by a `#include` macro.

Using the `restart` command in nested elements of imperative programming like for or while loops is possible. Since in most cases abandoning the current state of Sollya means altering a loop invariant, warnings of the impossibility of continuing a loop may follow unless the state is rebuilt.

**Example 1:**

```plaintext
> print(exp(x));
exp(x)
> a = 3;
> restart;
The tool has been restarted.
> print(x);
x
> a;
Warning: the identifier "a" is neither assigned to, nor bound to a library function nor external procedure, nor equal to the current free variable.
Will interpret "a" as "x".
x
```

**Example 2:**

> print(exp(x));
> exp(x)
> for i from 1 to 10 do {
>     print(i);
>     if (i == 5) then restart;
> };
1
2
3
4
5
The tool has been restarted.
Warning: the tool has been restarted inside a for loop.
The for loop will no longer be executed.

Example 3:

> print(exp(x));
> a = 3;
> for i from 1 to 10 do {
>     print(i);
>     if (i == 5) then {
>         restart;
>         i = 7;
>     };
> };
1
2
3
4
5
The tool has been restarted.
8
9
10
> print(x);  
x
> a;
Warning: the identifier "a" is neither assigned to, nor bound to a library function nor external procedure, nor equal to the current free variable.
Will interpret "a" as "x".
x

See also: quit [8.118], execute [8.46]

8.128 return

Name: return
indicates an expression to be returned in a procedure

Usage:

\[
\text{return expression : void}
\]

Parameters:

- \text{expression} represents the expression to be returned
Description:

- The keyword `return` allows for returning the (evaluated) expression `expression` at the end of a begin-end-block (-block) used as a Sollya procedure body. See `proc` for further details concerning Sollya procedure definitions.

  Statements for returning expressions using `return` are only possible at the end of a begin-end-block used as a Sollya procedure body. Only one `return` statement can be given per begin-end-block.

- If at the end of a procedure definition using `proc` no `return` statement is given, a `return void` statement is implicitly added. Procedures, i.e. procedure objects, when printed out in Sollya defined with an implicit `return void` statement are displayed with this statement explicitly given.

Example 1:

```plaintext
> succ = proc(n) { var res; res := n + 1; return res; };
> succ(5);
6
> succ;
proc(n)
begin
  var res;
  res := (n) + (1);
  return res;
end
```

Example 2:

```plaintext
> hey = proc(s) { print("Hello",s); };
> hey("world");
Hello world
> hey;
proc(s)
begin
  print("Hello", s);
  return void;
end
```

See also: `proc` (8.116), `void` (8.158)

8.129 revert

Name: `revert`

reverts a list.

Usage:

`revert(L) : list → list`

Parameters:

- `L` is a list.

Description:

- `revert(L)` returns the same list, but with its elements in reverse order.

- If `L` is an end-elliptic list, `revert` will fail with an error.

Example 1:
Example 2:

```plaintext
> revert([1, 1]);
[1, 1]
```

8.130  **rn**

Name: **RN**

constant representing rounding-to-nearest mode.

Description:

- **RN** is used in command `round` to specify that the value must be rounded to the nearest representable floating-point number.

Example 1:

```plaintext
> display=binary!;
> round(Pi,20,RN);
1.100100100001111111_2 * 2^(1)
```

See also: **RD** (8.121), **RU** (8.135), **RZ** (8.136), **round** (8.131)

8.131  **round**

Name: **round**

rounds a number to a floating-point format.

Usage:

```plaintext
round(x,n,mode) : (constant, integer, RD | RU | RN | RZ) → constant
```

Parameters:

- **x** is a constant to be rounded.
- **n** is the precision of the target format.
- **mode** is the desired rounding mode.

Description:

- **round(x,n,mode)** rounds **x** to a floating-point number with precision **n**, according to rounding-mode **mode**.

- Subnormal numbers are not handled. The range of possible exponents is the range used for all numbers represented in Sollya (e.g. basically the range used in the library MPFR). Please use the functions `double`, `doubleextended`, `doubledouble` and `tripledouble` for roundings to classical formats with their range of exponents.

Example 1:

```plaintext
> display=binary!;
> round(Pi,20,RN);
1.100100100001111111_2 * 2^(1)
```

Example 2:
8.132 roundcoefficients

Name: **roundcoefficients**

rounds the coefficients of a polynomial to classical formats.

Usage:

```
roundcoefficients(p, L) : (function, list) → function
```

Parameters:

- **p** is a function. Usually a polynomial.
- **L** is a list of formats.

Description:

- If **p** is a polynomial and **L** a list of floating-point formats, **roundcoefficients**(*p*, **L**) rounds each coefficient of **p** to the corresponding format in **L**.
- If **p** is not a polynomial, **roundcoefficients** does not do anything.
- If **L** contains other elements than **D**, **double**, **DD**, **doubledouble**, **TD** and **tripledouble**, an error occurs.
- The coefficients in **p** corresponding to **X**<sup>i</sup> is rounded to the format **L**[i]. If **L** does not contain enough elements (e.g. if `length(L) < degree(p) + 1`), a warning is displayed. However, the coefficients corresponding to an element of **L** are rounded. The last coefficients (that do not have a corresponding element in **L**) are kept with their own precision. If **L** contains too much elements, the last useless elements are ignored. In particular **L** may be end-elliptic in which case **roundcoefficients** has the natural behavior.

Example 1:

```
> p = exp(1) + x*(exp(2) + x*exp(3));
> display = binary!;
> roundcoefficients(p, [DD, D, D]);
1.010111111100001010100010100010100010100111011010000101111110110101
1.010111111110001010100010100010100010100111011010000101111110110101
00101010001000000010011101_2 * 2^(-1) + x * (1.11011000111010001001010111001010111011010010101001101010101111101101001010110010000001010111110110101111110110101
0000011_2 * 2^(-4))
> roundcoefficients(p, [DD, D, ...]);
1.010111111110001010100010100010100010100111011010000101111110110101
00101010001000000010011101_2 * 2^(-1) + x * (1.11011000111010001001010111001010111011010010101001101010101111101101001010110010000001010111110110101111110110101
0000011_2 * 2^(-4))
```

Example 2:

```
```

113
Example 3:

```plaintext
> p=exp(1) + x*(exp(2) + x*exp(3));
> verbosity=1!
> display=binary!
> roundcoefficients(p,[|DD,D|]);
Warning: the number of the given formats does not correspond to the degree of the given polynomial.
Warning: the 0th coefficient of the given polynomial does not evaluate to a floating-point constant without any rounding.
Will evaluate the coefficient in the current precision in floating-point before rounding to the target format.
Warning: the 1th coefficient of the given polynomial does not evaluate to a floating-point constant without any rounding.
Will evaluate the coefficient in the current precision in floating-point before rounding to the target format.
Warning: rounding may have happened.
1.0101101111110000101010001010010010111011001010010010010101110111011110110111010010101001101010101110111000101000000001001110011110100111100111100011101100010111001110001011000000111001011100101001_2 * 2^(-1))
```

See also: `double` [8.37], `doubledouble` [8.38], `tripledouble` [8.154]

### 8.133 roundcorrectly

**Name:** roundcorrectly

rounds an approximation range correctly to some precision

**Usage:**

```
roundcorrectly(range) : range → constant
```

**Parameters:**

- `range` represents a range in which an exact value lies

**Description:**

- Let `range` be a range of values, determined by some approximation process, safely bounding an unknown value `v`. The command `roundcorrectly(range)` determines a precision such that for this precision, rounding to the nearest any value in `range` yields to the same result, i.e. to the correct rounding of `v`.

  If no such precision exists, a warning is displayed and **roundcorrectly** evaluates to NaN.

**Example 1:**
Example 2:

```
> printbinary(roundcorrectly([1.010001_2; 1.0101_2]));
1.01_2
> printbinary(roundcorrectly([1.00001_2; 1.001_2]));
1._2
```

See also: `round` (8.131)

### 8.134 roundingwarnings

Name: **roundingwarnings**

global variable controlling whether or not there is a warning when roundings occur.

Description:

- **roundingwarnings** is a global variable. When its value is **on**, warnings are emitted in appropriate verbosity modes (see **verbosity**) when roundings occur. When its value is **off**, these warnings are suppressed.
- This mode depends on a verbosity of at least 1. See **verbosity** for more details.
- Default is **on** when the standard input is a terminal and **off** when **Sollya** input is read from a file.

Example 1:

```
> verbosity=1!;
> roundingwarnings = on;
Rounding warning mode has been activated.
> exp(0.1);
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
Warning: rounding has happened. The value displayed is a faithful rounding of the true result.
1.1051709180756476248117078264902466682245471947375
> roundingwarnings = off;
Rounding warning mode has been deactivated.
> exp(0.1);
1.1051709180756476248117078264902466682245471947375
```

See also: **on** (8.96), **off** (8.95), **verbosity** (8.157), **midpointmode** (8.88)

### 8.135 ru

Name: **RU**

constant representing rounding-upwards mode.

Description:

- **RU** is used in command **round** to specify that the value \( x \) must be rounded to the smallest floating-point number \( y \) such that \( x \leq y \).

Example 1:
> display=binary!;
> round(Pi,20,RU);
> 1.1001001000011111101_2 * 2^1

See also: **RZ** ([8.136]), **RD** ([8.121]), **RN** ([8.130]), **round** ([8.131])

### 8.136 rz

**Name:** RZ  
constant representing rounding-to-zero mode.

**Description:**  
- **RZ** is used in command `round` to specify that the value must be rounded to the closest floating-point number towards zero. It just consists in truncate the value to the desired format.

**Example 1:**

```
> display=binary!;
> round(Pi,20,RZ);
> 1.1001001000011111101_2 * 2^1
```

See also: **RD** ([8.121]), **RU** ([8.135]), **RN** ([8.130]), **round** ([8.131])

### 8.137 searchgal

**Name:** searchgal  
searches for a preimage of a function such that the rounding the image commits an error smaller than a constant

**Usage:**

```
searchgal(function, start, preimage precision, steps, format, error bound) : (function, constant, integer, integer, D|double|DD|doubledouble|DE|doubleextended|TD|tripledouble, constant) → list
searchgal(list of functions, start, preimage precision, steps, list of format, list of error bounds) : (list, constant, integer, integer, list, list) → list
```

**Parameters:**

- **function** represents the function to be considered  
- **start** represents a value around which the search is to be performed  
- **preimage precision** represents the precision (discretisation) for the eligible preimage values  
- **steps** represents the log2 of the number of search steps to be performed  
- **format** represents the format the image of the function is to be rounded to  
- **error bound** represents a upper bound on the relative rounding error when rounding the image  
- **list of functions** represents the functions to be considered  
- **list of formats** represents the respective formats the images of the functions are to be rounded to  
- **list of error bounds** represents a upper bound on the relative rounding error when rounding the image

**Description:**
The command `searchgal` searches for a preimage \( z \) of a function \( \text{function} \) or a list of functions \( \text{list of functions} \) such that \( z \) is a floating-point number with \( \text{preimage precision} \) significant mantissa bits and the image \( y \) of the function, respectively each image \( y_i \) of the functions, rounds to format \( \text{format} \) respectively to the corresponding format in \( \text{list of format} \) with a relative rounding error less than \( \text{error bound} \) respectively the corresponding value in \( \text{list of error bounds} \). During this search, at most \( 2^{\text{steps}} \) attempts are made. The search starts with a preimage value equal to \( \text{start} \). This value is then increased and decreased by 1 ulp in precision \( \text{preimage precision} \) until a value is found or the step limit is reached.

If the search finds an appropriate preimage \( z \), `searchgal` evaluates to a list containing this value. Otherwise, `searchgal` evaluates to an empty list.

Example 1:

```plaintext
> searchgal(log(x),2,53,15,DD,1b-112);
[1 1]
> searchgal(log(x),2,53,18,DD,1b-112);
[2.000000000038497205423482280704975128173828125]
```

Example 2:

```plaintext
> f = exp(x);
> s = searchgal(f,2,53,18,DD,1b-112);
> if (s != []) then {
>     v = s[0];
>     print("The rounding error is 2^","(evaluate(log2(abs(DD(f)/f - 1)),v),")");
> } else print("No value found");
```

The rounding error is 2^(-1.12106878438809380148206984258358542322113874177832e-2)

Example 3:

```plaintext
> searchgal([sin(x),cos(x)],1,53,15,[D,D],[1b-62,1b-60]);
[1.0000000000015949463971764998597258925437927246094]
```

### 8.138 simplify

Name: `simplify`
simplifies an expression representing a function

Usage:

```
simplify(function) : function → function
```

Parameters:

- `function` represents the expression to be simplified

Description:

- The command `simplify` simplifies constant subexpressions of the expression given in argument representing the function `function`. Those constant subexpressions are evaluated in using floating-point arithmetic with the global precision `prec`.

Example 1:
Example 2:

```plaintext
> prec = 20!;
> t = erf(0.5);
> s = simplify(erf(0.5));
> prec = 200!;
> t;
0.5204998778130465376827466538919645287364515757579637000588058
> s;
0.52050018310546875
```

See also: `simplifysafe` [8.139], `autosimplify` [8.14], `prec` [8.108], `evaluate` [8.45]

### 8.139 simplifysafe

**Name:** `simplifysafe`  
Simplifies an expression representing a function

**Usage:**

```plaintext
simplifysafe(function) : function → function
```

**Parameters:**

- `function` represents the expression to be simplified

**Description:**

- The command `simplifysafe` simplifies the expression given in argument representing the function `function`. The command `simplifysafe` does not endanger the safety of computations even in Sollya’s floating-point environment: the function returned is mathematically equal to the function `function`.

  Remark that the simplification provided by `simplifysafe` is not perfect: they may exist simpler equivalent expressions for expressions returned by `simplifysafe`.

**Example 1:**

```plaintext
> print(simplifysafe((6 + 2) + (5 + exp(0)) * x));
8 + 6 * x
```

**Example 2:**

```plaintext
> print(simplifysafe((log(x - x + 1) + asin(1))));
(pi) / 2
```

**Example 3:**

```plaintext
> print(simplifysafe((log(x - x + 1) + asin(1)) - (atan(1) * 2)));
(pi) / 2 - (pi) / 4 * 2
```

See also: `simplify` [8.138], `autosimplify` [8.14]
8.140  \( \text{sin} \)

Name: \( \text{sin} \)
the sine function.

Description:

- \( \text{sin} \) is the usual sine function.
- It is defined for every real number \( x \).

See also: \( \text{asin} \) (8.10), \( \text{cos} \) (8.24), \( \text{tan} \) (8.149)

8.141  \( \text{sinh} \)

Name: \( \text{sinh} \)
the hyperbolic sine function.

Description:

- \( \text{sinh} \) is the usual hyperbolic sine function: \( \sinh(x) = \frac{e^x - e^{-x}}{2} \).
- It is defined for every real number \( x \).

See also: \( \text{asinh} \) (8.11), \( \text{cosh} \) (8.25), \( \text{tanh} \) (8.150)

8.142  \( \text{sort} \)

Name: \( \text{sort} \)
sorts a list of real numbers.

Usage:

\[
\text{sort}(L) : \text{list} \rightarrow \text{list}
\]

Parameters:

- \( L \) is a list.

Description:

- If \( L \) contains only constant values, \( \text{sort}(L) \) returns the same list, but sorted increasingly.
- If \( L \) contains at least one element that is not a constant, the command fails with a type error.
- If \( L \) is an end-elliptic list, \( \text{sort} \) will fail with an error.

Example 1:

\[
> \text{sort}([1, 1]);
[1, 1]
> \text{sort}([[2,3,5,2,1,4]]);
[1, 2, 2, 3, 4, 5]\
\]

8.143  \( \text{sqrt} \)

Name: \( \text{sqrt} \)
square root.

Description:

- \( \text{sqrt} \) is the square root, e.g. the inverse of the function square: \( \sqrt{y} \) is the unique positive \( x \) such that \( x^2 = y \).
- It is defined only for \( x \) in \([0; +\infty]\).
8.144 string

Name: string
keyword representing a string type

Usage:

\[
\text{string} : \text{type type}
\]

Description:

- **string** represents the string type for declarations of external procedures by means of `externalproc`.

  Remark that in contrast to other indicators, type indicators like string cannot be handled outside the `externalproc` context. In particular, they cannot be assigned to variables.

See also: `externalproc` [8.52], `boolean` [8.17], `constant` [8.23], `function` [8.61], `integer` [8.73], `list of` [8.80], `range` [8.119]

8.145 subpoly

Name: subpoly
restricts the monomial basis of a polynomial to a list of monomials

Usage:

\[
\text{subpoly}(\text{polynomial, list}) : (\text{function, list}) \rightarrow \text{function}
\]

Parameters:

- **polynomial** represents the polynomial the coefficients are taken from
- **list** represents the list of monomials to be taken

Description:

- **subpoly** extracts the coefficients of a polynomial polynomial and builds up a new polynomial out of those coefficients associated to monomial degrees figuring in the list list.

If polynomial represents a function that is not a polynomial, subpoly returns 0.

If list is a list that is end-elliptic, let be j the last value explicitly specified in the list. All coefficients of the polynomial associated to monomials greater or equal to j are taken.

Example 1:

```plaintext
> p = taylor(exp(x),5,0);
> s = subpoly(p,[|1,3,5|]);
> print(p);
1 + x * (1 + x * (0.5 + x * (1 / 6 + x * (1 / 24 + x / 120))))
> print(s);
x * (1 + x^-2 * (1 / 6 + x^-2 / 120))
```

Example 2:

```plaintext
> p = remez(atan(x),10,[-1,1]);
> subpoly(p,[|1,3,5...|]);
x * (0.9998663294659189897581285958052433296267358727218 + x^-2 * (-0.330304785048612606064668353 + x^-2 * (0.18015929463652346799743775117895903961773054102026 + x * (-1.2170485832186602890617585649390033851985005594189e-14 + x * (-8.515635083370270299650536803770858918120961559704e-2 + x * (1.3968128476342339364451388757935284353552217389724e-14 + x * (2.0845114175434561643018447784809809559834125291788e-2 + x * (-5.681013101257943626569762242601132558407328558859e-15)))))))))
```
Example 3:

\[ \text{subpoly}(\exp(x), \{1,2,3\}); \]
\[ 0 \]

See also: \texttt{roundcoefficients} (8.132), \texttt{taylor} (8.151), \texttt{remez} (8.125)

8.146 \hspace{1em} \text{substitute}

Name: \text{substitute}

replace the occurrences of the free variable in an expression.

Usage:

\[ \text{substitute}(f,g) : (\text{function}, \text{function}) \rightarrow \text{function} \]
\[ \text{substitute}(f,t) : (\text{function}, \text{constant}) \rightarrow \text{constant} \]

Parameters:

- \( f \) is a function.
- \( g \) is a function.
- \( t \) is a real number.

Description:

- \( \text{substitute}(f,g) \) produces the function \((f \circ g) : x \mapsto f(g(x))\).
- \( \text{substitute}(f,t) \) is the constant \( f(t) \). Note that the constant is represented by its expression until it has been evaluated (exactly the same way as if you type the expression \( f \) replacing instances of the free variable by \( t \)).
- If \( f \) is stored in a variable \( F \). It is absolutely equivalent to writing \( F(g) \) or \( F(t) \).

Example 1:

\[ > f=\sin(x); \]
\[ > g=\cos(x); \]
\[ > \text{substitute}(f,g); \]
\[ \sin(\cos(x)) \]
\[ > f(g); \]
\[ \sin(\cos(x)) \]

Example 2:

\[ > a=1; \]
\[ > f=\sin(x); \]
\[ > \text{substitute}(f,a); \]
0.841470984807896506652502321630298999622566306079837
\[ > f(a); \]
0.841470984807896506652502321630298999622566306079837

8.147 \hspace{1em} \text{sup}

Name: \text{sup}

gives the upper bound of an interval.

Usage:
\[ \text{sup}(I) : \text{range} \rightarrow \text{constant} \]
\[ \text{sup}(x) : \text{constant} \rightarrow \text{constant} \]

Parameters:
- \( I \) is an interval.
- \( x \) is a real number.

Description:
- Returns the upper bound of the interval \( I \). Each bound of an interval has its own precision, so this command is exact, even if the current precision is too small to represent the bound.
- When called on a real number \( x \), \( \text{sup} \) considers it as an interval formed of a single point: \([x, x]\). In other words, \( \text{sup} \) behaves like the identity.

Example 1:
\[
\begin{align*}
> & \text{sup}([1;3]); \\
& 3 \\
> & \text{sup}(5); \\
& 5
\end{align*}
\]

Example 2:
\[
\begin{align*}
> & \text{display}=\text{binary}!; \\
> & I=[0; \ 0.111110000011111_2]; \\
> & \text{sup}(I); \\
& 1.11110000011111_2 \ast 2^(-1) \\
> & \text{prec}=12!; \\
> & \text{sup}(I); \\
& 1.11110000011111_2 \ast 2^(-1)
\end{align*}
\]

See also: \( \text{inf} \) (8.71), \( \text{mid} \) (8.87)

8.148 \ tail

Name: \ tail

\textit{gives the tail of a list.}

Usage:
\[
\text{tail}(L) : \text{list} \rightarrow \text{any type}
\]

Parameters:
- \( L \) is a list.

Description:
- \( \text{tail}(L) \) returns the list \( L \) without its first element.
- If \( L \) is empty, the command will fail with an error.
- \( \text{tail} \) can also be used with end-elliptic lists. In this case, the result of \( \text{tail} \) is also an end-elliptic list.

Example 1:
\[
\begin{align*}
> & \text{tail}([1,2,3]); \\
& [2, 3] \\
> & \text{tail}([1,2...]); \\
& [2...]
\end{align*}
\]

See also: \( \text{head} \) (8.65)
8.149 tan

Name: tan

the tangent function.

Description:

- **tan** is the tangent function, defined by \( \tan(x) = \frac{\sin(x)}{\cos(x)} \).
- It is defined for every real number \( x \) that is not of the form \( n\pi + \pi/2 \) where \( n \) is an integer.

See also: atan 8.12, cos 8.24, sin 8.140

8.150 tanh

Name: tanh

the hyperbolic tangent function.

Description:

- **tanh** is the hyperbolic tangent function, defined by \( \tanh(x) = \frac{\sinh(x)}{\cosh(x)} \).
- It is defined for every real number \( x \).

See also: atanh 8.13, cosh 8.25, sinh 8.141

8.151 taylor

Name: taylor

computes a Taylor expansion of a function in a point

Usage:

\[
taylor(\text{function}, \text{degree}, \text{point}) : (\text{function}, \text{integer}, \text{constant}) \rightarrow \text{function}
\]

Parameters:

- **function** represents the function to be expanded
- **degree** represents the degree of the expansion to be delivered
- **point** represents the point in which the function is to be developped

Description:

- The command **taylor** returns an expression that is a Taylor expansion of function **function** in point **point** having the degree **degree**.

Let \( f \) be the function **function**, \( t \) be the point **point** and \( n \) be the degree **degree**. Then, **taylor**(function,degree,point) evaluates to an expression mathematically equal to

\[
\sum_{i=0}^{n} \frac{f^{(i)}(t)}{i!} (x-t)^i
\]

Remark that **taylor** evaluates to 0 if the degree **degree** is negative.

Example 1:

```plaintext
> print(taylor(exp(x),5,0));
1 + x * (1 + x * (0.5 + x * (1 / 6 + x * (1 / 24 + x / 120))))
```

Example 2:
Example 3:

```plaintext
> print(taylor(erf(x),6,0));
> x * (1 / sqrt((pi) / 4) + x^2 * ((sqrt((pi) / 4) * 4 / (pi) * (-2)) / 6 + x^2 * (sqrt((pi) / 4) * 4 / (pi) * 12) / 120))
```

See also: `remez (8.125)`

### 8.152 taylorrecursions

Name: `taylorrecursions`

controls the number of recursion steps when applying Taylor’s rule.

Description:

- `taylorrecursions` is a global variable. Its value represents the number of steps of recursion that are used when applying Taylor’s rule. This rule is applied by the interval evaluator present in the core of Sollya (and particularly visible in commands like `infnorm`).

- To improve the quality of an interval evaluation of a function $f$, in particular when there are problems of decorrelation, the evaluator of Sollya uses Taylor’s rule: $f([a,b]) \subseteq f(m) + [a - m, b - m] \cdot f’([a, b])$ where $m = \frac{a + b}{2}$. This rule can be applied recursively. The number of step in this recursion process is controlled by `taylorrecursions`.

- Setting `taylorrecursions` to 0 makes Sollya use this rule only one time; setting it to 1 makes Sollya use the rule two times, and so on. In particular: the rule is always applied at least once.

Example 1:

```plaintext
> f=exp(x);
> p=remez(f,3,[0;1]);
> taylorrecursions=0;
> evaluate(f-p, [0;1]);
The number of recursions for Taylor evaluation has been set to 0.
> evaluate(f-p, [0;1]);
[-0.46839364816303627522963565754743169862357620487739;0.4694778175466708649168244358303517779]
> taylorrecursions=1;
The number of recursions for Taylor evaluation has been set to 1.
> evaluate(f-p, [0;1]);
[-0.1381311495387910066337940912697015317218647208804;0.1392152843375136903505684015504189989844403238444]
```

### 8.153 timing

Name: `timing`

global variable controlling timing measures in Sollya.

Description:

- `timing` is a global variable. When its value is on, the time spent in each command is measured and displayed (for verbosity levels higher than 1).

Example 1:
> verbosity=1!;
> timing=on;
Timing has been activated.
> p=remez(sin(x),10,[-1;1]);
Information: Remez: computing the matrix spent 2 ms
Information: Remez: computing the quality of approximation spent 14 ms
Information: Remez: computing the matrix spent 2 ms
Information: Remez: computing the quality of approximation spent 14 ms
Information: Remez: computing the matrix spent 2 ms
Information: Remez: computing the quality of approximation spent 14 ms
Information: computing a minimax approximation spent 92 ms
Information: assignment spent 92 ms
Information: full execution of the last parse chunk spent 92 ms

See also: on (8.96), off (8.95)

8.154 tripledouble

Names: tripledouble, TD
represents a number as the sum of three IEEE doubles.

Description:

- **tripledouble** is both a function and a constant.

  - As a function, it rounds its argument to the nearest number that can be written as the sum of three double precision numbers.

  - The algorithm used to compute $\text{tripledouble}(x)$ is the following: let $x_h = \text{double}(x)$ and let $x_l = \text{doubledouble}(x-x_h)$. Return the number $x_h+x_l$. Note that if the current precision is not sufficient to represent exactly $x_h+x_l$, a rounding will occur and the result of $\text{tripledouble}(x)$ will be useless.

  - As a constant, it symbolizes the triple-double precision format. It is used in contexts when a precision format is necessary, e.g. in the commands $\text{roundcoefficients}$ and $\text{implementpoly}$. See the corresponding help pages for examples.

Example 1:

```plaintext
> verbosity=1!;
> a = 1 + 2^(-55)+2^(-115);
> TD(a);
Warning: rounding a value computed on less than 159 bits to triple-double precision
1.00000000000000002775557561562891353466491600711096
> prec=110!;
> TD(a);
Warning: rounding a value computed on less than 159 bits to triple-double precision
Warning: double rounding occurred on invoking the triple-double rounding operator.
Try to increase the working precision.
1.0000000000000000027755575615628913
```

See also: double (8.37), doubleextended (8.39), doubledouble (8.38), roundcoefficients (8.132), implementpoly (8.70)
8.155  true

Name: true
the boolean value representing the truth.

Description:

• true is the usual boolean value.

Example 1:

```plaintext
> true && false;
false
> 2>1;
true
```

See also: false (8.53), && (8.6), || (8.97)

8.156  var

Name: var
declaration of a local variable in a scope

Usage:

```plaintext
var identifier1, identifier2,... , identifierm : void
```

Parameters:

• identifier1, identifier2,... , identifierm represent variable identifiers

Description:

• The keyword var allows for the declaration of local variables identifier1 through identifierm in a begin-end-block ({}-block). Once declared as a local variable, an identifier will shadow identifiers declared in higher scopes and undeclared identifiers available at top-level.

  Variable declarations using var are only possible in the beginning of a begin-end-block. Several var statements can be given. Once another statement is given in a begin-end-block, no more var statements can be given.

  Variables declared by var statements are dereferenced as error until they are assigned a value.

Example 1:

```plaintext
> exp(x);
exp(x)
> a = 3;
> {var a, b; a=5; b=3; {var a; var b; b = true; a = 1; a; b;}; a; b; }
 1
  true
  5
  3
> a;
3
```

See also: error (8.44)
8.157 verbosity

Name: verbosity

global variable controlling the quantity of information displayed by commands.

Description:

- verbosity accepts any integer value. At level 0, commands do not display anything on standard out. Note that very critical information may however be displayed on standard err.

- Default level is 1. It displays important information such as warnings when roundings happen.

- For higher levels more information is displayed depending on the command.

Example 1:

```
> verbosity=0;!  
> 1.2+toto;   
error
> verbosity=1;!  
> 1.2+toto;   
Warning: Rounding occurred when converting the constant "1.2" to floating-point with 165 bits.  
If safe computation is needed, try to increase the precision.   
Warning: at least one of the given expressions or a subexpression is not correctly typed   
or its evaluation has failed because of some error on a side-effect.   
error
> verbosity=2;!  
> 1.2+toto;   
Warning: Rounding occurred when converting the constant "1.2" to floating-point with 165 bits.  
If safe computation is needed, try to increase the precision.   
Warning: at least one of the given expressions or a subexpression is not correctly typed   
or its evaluation has failed because of some error on a side-effect.   
Information: the expression or a partial evaluation of it has been the following:   
(1.19999999999999999999999999999999999999999999999999) + ("toto")   
error
```

See also: roundingwarnings [8.134]

8.158 void

Name: void

the functional result of a side-effect or empty argument resp. the corresponding type

Usage:

```
void : void | type type
```

Description:

- The variable void represents the functional result of a side-effect or an empty argument. It is used only in combination with the applications of procedures or identifiers bound through externalproc to external procedures.

The void result produced by a procedure or an external procedure is not printed at the prompt. However, it is possible to print it out in a print statement or in complex data types such as lists.
The **void** argument is implicit when giving not argument to a procedure or an external procedure when applied. It can be explicitly given nevertheless. For example, suppose that foo is a procedure or an external procedure with a void argument. Then foo() and foo(void) are correct calls to foo.

- **void** is used also as a type identifier for **externalproc**. Typically, an external procedure taking **void** as an argument or returning **void** is bound with a signature **void** − > some type or some type − > **void**. See **externalproc** for more details.

Example 1:

```plaintext
> print(void);
void
> void;
```

Example 2:

```plaintext
> hey = proc() { print("Hello world."); };
> hey;
proc()
begin
print("Hello world.");
return void;
end
> hey();
Hello world.
> hey(void);
Hello world.
> print(hey());
Hello world.
void
```

Example 3:

```plaintext
> bashexecute("gcc -fPIC -Wall -c externalprocvoidexample.c");
> bashexecute("gcc -fPIC -shared -o externalprocvoidexample externalprocvoidexample.o");
> externalproc(foo, "./externalprocvoidexample", void -> void);
> foo;
foo(void) -> void
> foo();
Hello from the external world.
> foo(void);
Hello from the external world.
> print(foo());
Hello from the external world.
void
```

See also: **error** [8.44], **proc** [8.116], **externalproc** [8.52]

### 8.159 worstcase

**Name:** worstcase

searches for hard-to-round

**Usage:**
**worstcase***(function, preimage precision, preimage exponent range, image precision, error bound) :
  (function, integer, range, integer, constant) → void

**worstcase***(function, preimage precision, preimage exponent range, image precision, error bound, filename) : (function, integer, range, integer, constant, string) → void

Parameters:

- **function** represents the function to be considered
- **preimage precision** represents the precision of the preimages
- **preimage exponent range** represents the exponents in the preimage format
- **image precision** represents the precision of the format the images are to be rounded to
- **error bound** represents the upper bound for the search w.r.t. the relative rounding error
- **filename** represents a character sequence containing a filename

Description:

- The **worstcase** command is deprecated. It searches hard-to-round cases of a function. The command **searchgal** has a comparable functionality.

Example 1:

```
> worstcase(exp(x),24,[1,2],24,1b-26);
prec = 165
x = 1.9999988079071044921875 f(x) = 7.3890552520751953125 eps = 4
 599860142346695596184695493764120138001954979037e-9 = 2^(-27.695763)
 83793955341787812515087072e-8 = 2^(-26.043720)
```

See also: **round** (8.131), **searchgal** (8.137), **evaluate** (8.45)

### 8.160 write

**Name:** write

prints an expression without separators

**Usage:**

```
write(expr1,...,exprn) : (any type,..., any type) → void
write(expr1,...,exprn) > filename : (any type,..., any type, string) → void
write(expr1,...,exprn) >> filename : (any type,...,any type, string) → void
```

Parameters:

- **expr** represents an expression
- **filename** represents a character sequence indicating a file name

Description:

- **write(expr1,...,exprn)** prints the expressions expr1 through exprn. The character sequences corresponding to the expressions are concatenated without any separator. No newline is displayed at the end. In contrast to **print**, **write** expects the user to give all separators and newlines explicitly.

If a second argument **filename** is given after a single " ", the displaying is not output on the standard output of Sollya but if in the file **filename** that get newly created or overwritten. If a double " ">" is given, the output will be appended to the file **filename**.

129
The global variables \texttt{display}, \texttt{midpointmode} and \texttt{fullparentheses} have some influence on the formatting of the output (see \texttt{display}, \texttt{midpointmode} and \texttt{fullparentheses}).

Remark that if one of the expressions \texttt{expri} given in argument is of type \texttt{string}, the character sequence \texttt{expri} evaluates to is displayed. However, if \texttt{expri} is of type \texttt{list} and this list contains a variable of type \texttt{string}, the expression for the list is displayed, i.e. all character sequences get displayed surrounded by quotes (‘“’). Nevertheless, escape sequences used upon defining character sequences are interpreted immediately.

Example 1:

\begin{verbatim}
> write(x + 2 + exp(sin(x)));
> write("Hello\n");
x + 2 + exp(sin(x))Hello
> write("Hello","world\n");
Hello world
> write("Hello","you", 4 + 3, "other persons.\n");
Hello you7other persons.
\end{verbatim}

Example 2:

\begin{verbatim}
> write("Hello","\n");
Hello
> write(["Hello"|],"\n");
["Hello"]
> s = "Hello";
> write(s,[[s|],"\n");
Hello["Hello"]
> t = "Hello\tyou";
> write(t,[[t|],"\n");
Hello you["Hello you"]
\end{verbatim}

Example 3:

\begin{verbatim}
> write(x + 2 + exp(sin(x))) > "foo.sol";
> readfile("foo.sol");
x + 2 + exp(sin(x))
\end{verbatim}

Example 4:

\begin{verbatim}
> write(x + 2 + exp(sin(x))) >> "foo.sol";
\end{verbatim}

See also: \texttt{print} \footnote{8.111}, \texttt{printexpansion} \footnote{8.112}, \texttt{printhexa} \footnote{8.14}, \texttt{printfloat} \footnote{8.13}, \texttt{printxml} \footnote{8.115}, \texttt{readfile} \footnote{8.122}, \texttt{autosimplify} \footnote{8.14}, \texttt{display} \footnote{8.35}, \texttt{midpointmode} \footnote{8.88}, \texttt{fullparentheses} \footnote{8.60}, \texttt{evaluate} \footnote{8.45}
