Appendix: interval arithmetic philosophy in Sollya

Appendix: the Sollya library

9 Appendix: interval arithmetic philosophy in Sollya

10 Appendix: the Sollya library
1 Compilation and installation of Sollya

Sollya comes in two flavors:

- Either as an interactive tool. This is achieved by running the Sollya executable file.
- Or as a C library that provides all the features of the tool within the C programming language.

The installation of the tool and the library follow the same steps, described below. The present documentation focuses more on the interactive tool. As a matter of fact, the library works exactly the same way as the tool, so it is necessary to know a little about the tool in order to correctly use the library. The reader who is only interested in the library should at least read the following Sections 2, 3 and 5. A documentation specifically describing the library usage is available in Appendix 10 at the end of the present documentation.

1.1 Compilation dependencies

The Sollya distribution can be compiled and installed using the usual ./configure, make, make install procedure. Besides a C and a C++ compiler, Sollya needs the following software libraries and tools to be installed. The ./configure script checks for the installation of the libraries. However Sollya will build without error if some of its external tools are not installed. In this case an error will be displayed at runtime.

- GMP
- MPFR
- MPFI
- fplll
- libxml2
- gnuplot (external tool)

The use of the external tool rlwrap is highly recommended but not required to use the Sollya interactive tool. Use the -A option of rlwrap for correctly displayed ANSI X3.64/ ISO/IEC 6429 colored prompts (see below).
1.2 Sollya command line options

Sollya can read input on standard input or in a file whose name is given as an argument when Sollya is invoked. The tool will always produce its output on standard output, unless specifically instructed by a particular Sollya command that writes to a file. The following lines are valid invocations of Sollya, assuming that bash is used as a shell:

```
~/% sollya
...
~/% sollya myfile.sollya
...
~/% sollya < myfile.sollya
```

If a file given as an input does not exist, an error message is displayed.

All configurations of the internal state of the tool are done by commands given on the Sollya prompt or in Sollya scripts. Nevertheless, some command line options are supported; they work at a very basic I/O-level and can therefore not be implemented as commands.

The following options are supported when calling Sollya:

- **--donotmodifystacksize**: When invoked, Sollya tries to increase the stack size that is available to a user process to the maximum size supported by the kernel. On some systems, the correspondent ioctl does not work properly. Use the option to prevent Sollya from changing the stack size.

- **--flush**: When this option is given, Sollya will flush all its input and output buffers after parsing and executing each command resp. sequence of commands. This option is needed when pipes are used to communicate with Sollya from another program.

- **--help**: Prints help on the usage of the tool and quits.

- **--nocolor**: Sollya supports coloring of the output using ANSI X3.64/ ISO/IEC 6429 escape sequences. Coloring is deactivated when Sollya is connected on standard input to a file that is not a terminal. This option forces the deactivation of ANSI coloring. This might be necessary on very old grey-scale terminals or when encountering problems with old versions of rlwrap.

- **--noprompt**: Sollya prints a prompt symbol when connected on standard input to a pseudo-file that is a terminal. The option deactivates the prompt.

- **--oldautoprint**: The behaviour of an undocumented feature for displaying values has changed in Sollya from version 1.1 to version 2.0. The old feature is deprecated. If you wish to use it nevertheless, use this deprecated option.

- **--oldrlwrapcompatible**: This option is deprecated. It makes Sollya emit a non ANSI X3.64 compliant coloring escape sequence for making it compatible with versions of rlwrap that do not support the -A option. The option is considered a hack since it is known to garble the output of the tool under some particular circumstances.

- **--warninfile[append] <file>**: Normally, Sollya emits warning and information messages together with all other displayed information on either standard output or standard error. This option allows all warning and information messages to get redirected to a file. The filename to be used must be given after the option. When --warninfile is used, the existing content (if any) of the file is first removed before writing to the file. With --warninfileappend, the messages are appended to an existing file. Even if coloring is used for the displaying all other Sollya output, no coloring sequences are ever written to the file. Let us emphasize on the fact that any file of a unixoid system can be used for output, for instance also a named pipe. This allows for error messaging to be performed on a separate terminal. The use of this option is mutually exclusive with the --warnonstderr option.

- **--warnonstderr**: Normally, Sollya prints warning and information messages on standard output, using a warning color when coloring is activated. When this option is given, Sollya will output all warning and information messages on standard error. Coloring will be used even on standard output.
error, when activated. The use of this option is mutually exclusive with the \texttt{--warninfile[append]} option.

## 2 Introduction

\textbf{Sollya} is an interactive tool for handling numerical functions and working with arbitrary precision. It can evaluate functions accurately, compute polynomial approximations of functions, automatically implement polynomials for use in math libraries, plot functions, compute infinity norms, etc. \textbf{Sollya} is also a full-featured script programming language with support for procedures etc.

Let us begin this manual with an example. \textbf{Sollya} does not allow command line edition; since this may quickly become uncomfortable, we highly suggest to use the \texttt{rlwrap} tool with \textbf{Sollya}:

```
/*% rlwrap -A sollya
>
Sollya manipulates only functions in one variable. The first time that an unbound variable is used, this name is fixed. It will be used to refer to the free variable. For instance, try

```
> f = \sin(x)/x;
> g = \cos(y)-1;
Warning: the identifier "y" is neither assigned to, nor bound to a library function nor external procedure, nor equal to the current free variable. Will interpret "y" as "x".
> g;
\cos(x) - 1
```

Now, the name \texttt{x} can only be used to refer to the free variable:

```
> x = 3;
Warning: the identifier "x" is already bound to the free variable, to a library function, library constant or to an external procedure. The command will have no effect.
Warning: the last assignment will have no effect.
```

If you really want to unbind \texttt{x}, you can use the \texttt{rename} command and change the name of the free variable:

```
> rename(x,y);
Information: the free variable has been renamed from "x" to "y".
> g;
\cos(y) - 1
> x=3;
> x;
3
```

\textbf{Sollya} has a reserved keyword that can always be used to refer to the free variable. This keyword is \texttt{\_x\_.} This is particularly useful in contexts when the name of the variable is not known: typically when referring to the free variable in a pattern matching or inside a procedure.

```
> f == \sin(\_x\_)/\_x\_;
true
```

As you have seen, you can name functions and easily work with them. The basic thing to do with a function is to evaluate it at some point:
> f(-2);
Warning: rounding has happened. The value displayed is a faithful rounding to 165 bits of the true result.
0.45464871341284084769800993295587242135112748572394
> evaluate(f,-2);
0.45464871341284084769800993295587242135112748572394

The printed value is generally a faithful rounding of the exact value at the working precision (i.e. one of the two floating-point numbers enclosing the exact value). Internally Sollya represents numbers as floating-point numbers in arbitrary precision with radix 2: the fact that a faithful rounding is performed in binary does not imply much on the exactness of the digits displayed in decimal. The working precision is controlled by the global variable `prec`:

> prec;
165
> prec=200;
The precision has been set to 200 bits.
> prec;
200
> f(-2);
Warning: rounding has happened. The value displayed is a faithful rounding to 200 bits of the true result.
0.4546487134128408476980099329558724213511274857239451341894865

Sometimes a faithful rounding cannot easily be computed. In such a case, a value is printed that was obtained using floating-point approximations without control on the final accuracy:

> log2(5)/log2(17) - log(5)/log(17);
Warning: rounding may have happened.
If there is rounding, the displayed value is *NOT* guaranteed to be a faithful rounding of the true result.
0

The philosophy of Sollya is: *Whenever something is not exact, print a warning.* This explains the warnings in the previous examples. If the result can be shown to be exact, there is no warning:

> sin(0);
0

Let us finish this Section with a small complete example that shows a bit of what can be done with Sollya:

The tool has been restart
you affect a value to a global variable, a message is always printed even if verbosity is set to 0. In order

to silently affect a global variable, use !:

```
> prec=30;
The precision has been set to 30 bits.
> prec=30!;
```

For conviviality reasons, values are displayed in decimal by default. This lets a normal human being
understand the numbers they manipulate. But since constants are internally represented in binary, this
causes permanent conversions that are sources of roundings. Thus you are losing in accuracy and Sollya
is always complaining about inexact results. If you just want to store or communicate your results (to
another tool for instance) you can use bit-exact representations available in Sollya. The global variable
display defines the way constants are displayed. Here is an example of the five available modes:

```
> prec=30!;
> a = 17.25;
> display=decimal;
Display mode is decimal numbers.
> a;
1.725e1
> display=binary;
Display mode is binary numbers.
> a;
1.000101_2 * 2^(-4)
> display=powers;
Display mode is dyadic numbers in integer-power-of-2 notation.
> a;
69 * 2^(-2)
> display=dyadic;
Display mode is dyadic numbers.
> a;
69b-2
> display=hexadecimal;
Display mode is hexadecimal numbers.
> a;
0x1.14p4
```

Please keep in mind that it is possible to maintain the general verbosity level at some higher setting
while deactivating all warnings on roundings. This feature is controlled using the roundingwarnings
global variable. It may be set to on or off. By default, the warnings are activated (roundingwarnings
= on) when Sollya is connected on standard input to a pseudo-file that represents a terminal. They are
deactivated when Sollya is connected on standard input to a real file. See 8.158 for further details; the
behavior is illustrated with examples there.

As always, the symbol e means \times 10^2. The same way the symbol b means \times 2^2. The symbol p
means \times 2^2 and is used only with the 0x prefix. The prefix 0x indicates that the digits of the following
number until a symbol p or white-space are hexadecimal. The suffix _2 indicates to Sollya that the
previous number has been written in binary. Sollya can parse these notations even if you are not in the
corresponding display mode, so you can always use them.

You can also use memory-dump hexadecimal notation frequently used to represent IEEE 754 double
and single precision numbers. Since this notation does not allow for exactly representing numbers with
arbitrary precision, there is no corresponding display mode. However, the commands printdouble
respectively printsingle round the value to the nearest double respectively single. The number is
then printed in hexadecimal as the integer number corresponding to the memory representation of the
IEEE 754 double or single number:
Sollya can parse these memory-dump hexadecimal notation back in any display mode. The difference of this memory-dump notation with the hexadecimal notation (as defined above) is made by the presence or absence of a p indicator.

4 Variables

As already explained, Sollya can manipulate variate functional expressions in one variable. These expressions contain a unique free variable the name of which is fixed by its first usage in an expression that is not a left-hand-side of an assignment. This global and unique free variable is a variable in the mathematical sense of the term.

Sollya also provides variables in the sense programming languages give to the term. These variables, which must be different in their name from the global free variable, may be global or declared and attached to a block of statements, i.e. a begin-end-block. These programming language variables may hold any object of the Sollya language, as for example functional expressions, strings, intervals, constant values, procedures, external functions and procedures, etc.

Global variables need not to be declared. They start existing, i.e. can be correctly used in expressions that are not left-hand-sides of assignments, when they are assigned a value in an assignment. Since they are global, this kind of variables is recommended only for small Sollya scripts. Larger scripts with code reuse should use declared variables in order to avoid name clashes for example in loop variables.

Declared variables are attached to a begin-end-block. The block structure builds scopes for declared variables. Declared variables in inner scopes shadow (global and declared) variables of outer scopes. The global free variable, i.e. the mathematical variable for variate functional expressions in one variable, cannot be shadowed. Variables are declared using the var keyword. See section 8.188 for details on its usage and semantic.

The following code examples illustrate the use of variables.
Let us state that a variable identifier, just as every identifier in Sollya, contains at least one character, starts with a ASCII letter and continues with ASCII letters or numerical digits.

5 Data types

Sollya has a (very) basic system of types. If you try to perform an illicit operation (such as adding a number and a string, for instance), you will get a typing error. Let us see the available data types.

5.1 Booleans

There are two special values true and false. Boolean expressions can be constructed using the boolean connectors && (and), || (or), ! (not), and comparisons.

The comparison operators <, <=, > and >= can only be used between two numbers or constant expressions.

The comparison operators == and != are polymorphic. You can use them to compare any two objects, like two strings, two intervals, etc. As a matter of fact, polymorphism is allowed on both sides: it is possible to compare objects of different type. Such objects of different type, as they can never be syntactically equal, will always compare unequal (see exception for error, section 8.54) and never equal.

It is important to remember that testing the equality between two functions will return true if and only if the expression trees representing the two functions are exactly the same. See 8.54 for an exception concerning the special object error. Example:

> 1+x==1+x;  
true
5.2 Numbers

Sollya represents numbers as binary multi-precision floating-point values. For integer values and values in dyadic, binary, hexadecimal or memory dump notation, it automatically uses a precision needed for representing the value exactly (unless this behaviour is overridden using the syntax given below). Additionally, automatic precision adaption takes place for all integer values (even in decimal notation) written without the exponent sign $e$ or with the exponent sign $e$ and an exponent sufficiently small that they are less than $10^{999}$. Otherwise the values are represented with the current precision $\texttt{prec}$. When a number must be rounded, it is rounded to the precision $\texttt{prec}$ before the expression get evaluated:

```plaintext
> \texttt{prec=12!};
> 4097.1;
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
4098
> 4098.1;
Warning: Rounding occurred when converting the constant "4098.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
4098
> 4098.1+1;
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
4099
```

As a matter of fact, each variable has its own precision that corresponds to its intrinsic precision or, if it cannot be represented, to the value of $\texttt{prec}$ when the variable was set. Thus you can work with variables having a precision higher than the current precision.

The same way, if you define a function that refers to some constant, this constant is stored in the function with the current precision and will keep this value in the future, even if $\texttt{prec}$ becomes smaller.

If you define a function that refers to some variable, the precision of the variable is kept, independently of the current precision:

```plaintext
> \texttt{prec = 50!};
> a = 4097.1;
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 50 bits.
If safe computation is needed, try to increase the precision.
> \texttt{prec = 12!};
> f = x + a;
> g = x + 4097.1;
Warning: Rounding occurred when converting the constant "4097.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
> \texttt{prec = 120};
The precision has been set to 120 bits.
> f;
4.09709999999998544808477163314819335e3 + x
> g;
4098 + x
```

In some rare cases, it is necessary to read in decimal constants with a particular precision being used in the conversion to the binary floating-point format, which Sollya uses. Setting $\texttt{prec}$ to that precision may prove to be an insufficient means for doing so, for example when several different precisions have to
be used in one expression. For these rare cases, Sollya provides the following syntax: decimal constants may be written \$\%\text{precision}\%\text{constant}\$, where \text{precision} is a constant integer, written in decimal, and \text{constant} is the decimal constant. Sollya will convert the constant \text{constant} with precision \text{precision}, regardless of the global variable \text{prec} and regardless if \text{constant} is an integer or would otherwise be representable.

\begin{verbatim}
> prec = 24;
The precision has been set to 24 bits.
> a = 0.1;
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 24 bits.
If safe computation is needed, try to increase the precision.
> b = 33554433;
> prec = 64;
The precision has been set to 64 bits.
> display = binary;
Display mode is binary numbers.
> a;
1.100110011001100110011001\_2 \times 2^\text{(-4)}
> 0.1;
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 64 bits.
If safe computation is needed, try to increase the precision.
1.100110011001100110011001\_2 \times 2^\text{(-4)}
> \%24\%0.1;
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 24 bits.
If safe computation is needed, try to increase the precision.
1.100110011001100110011001\_2 \times 2^\text{(-4)}
> c = 33554433;
> b;
1.00000000000000000000000\_2 \times 2^\text{(25)}
> c;
1.00000000000000000000000\_2 \times 2^\text{(25)}
> \%24\%33554433;
Warning: Rounding occurred when converting the constant "33554433" to floating-point with 24 bits.
If safe computation is needed, try to increase the precision.
1_2 \times 2^\text{(25)}
> 

Sollya is an environment that uses floating-point arithmetic. The IEEE 754-2008 standard on floating-point arithmetic does not only define floating-point numbers that represent real numbers but also floating-point data representing infinities and Not-a-Numbers (NaNs). Sollya also supports infinities and NaNs in the spirit of the IEEE 754-2008 standard without taking the standard’s choices literally.

- Signed infinities are available through the Sollya objects infty, -infty, @Inf@ and -@Inf@.
- Not-a-Numbers are supported through the Sollya objects NaN and @NaN@. Sollya does not have support for NaN payloads, signaling or quiet NaNs or signs of NaNs. Signaling NaNs are supported on input for single and double precision memory notation (see section 3). However, they immediately get converted to plain Sollya NaNs.

The evaluation of an expression involving a NaN or the evaluation of a function at a point being NaN always results in a NaN.
Infinites are considered to be the limits of expressions tending to infinity. They are supported as
bounds of intervals in some cases. However, particular commands might prohibit their use even though
there might be a mathematical meaning attached to such expressions. For example, while Sollya will
evaluate expressions such as \( \lim_{x \to -\infty} e^x \), expressed e.g. through \texttt{evaluate(exp(x),[-infty;0])}, it will
not accept to compute the (finite) value of
\[
\int_{-\infty}^{0} e^x \, dx.
\]

The following examples give an idea of what can be done with Sollya infinities and NaNs. Here is
what can be done with infinities:

\begin{verbatim}
> f = exp(x) + 5;
> f(-infty);
5
> evaluate(f,[infty;infty]);
[5;@Inf@]
> f(infty);
@Inf@
> [-infty;5] * [3;4];
[-@Inf@;20]
> -infty < 5;
true
> log(0);
-@Inf@
> [log(0);17];
Warning: the given expression is not a constant but an expression to evaluate
and a faithful evaluation is not possible.
Will use a plain floating-point evaluation, which might yield a completely wrong
value.
Warning: inclusion property is satisfied but the diameter may be greater than th
e least possible.
[-@Inf@;17]
> 
\end{verbatim}

And the following example illustrates NaN behavior.
> 3/0;
Warning: the given expression is undefined or numerically unstable.
@NaN@
> (-3)/0;
Warning: the given expression is undefined or numerically unstable.
@NaN@
> infty/infty;
Warning: the given expression is undefined or numerically unstable.
@NaN@
> infty + infty;
@Inf@
> infty - infty;
Warning: the given expression is undefined or numerically unstable.
@NaN@
> f = exp(x) + 5;
> f(NaN);
@NaN@
> NaN == 5;
false
> NaN == NaN;
false
> NaN != NaN;
false
> X = "Vive la Republique!";
> !(X == X);
false
> X = 5;
> !(X == X);
false
> X = NaN;
> !(X == X);
true
>

5.3 Rational numbers and rational arithmetic

The Sollya tool is mainly based on floating-point arithmetic: wherever possible, floating-point algorithms, including algorithms using interval arithmetic, are used to produce approximate but safe results. For some particular cases, floating-point arithmetic is not sufficient: some algorithms just require natural and rational numbers to be handled exactly. More importantly, for these applications, it is required that rational numbers be displayed as such.

Sollya implements a particular mode that offers a lightweight support for rational arithmetic. When needed, it can be enabled by assigning on to the global variable rationalmode. It is disabled by assigning off; the default is off.

When the mode for rational arithmetic is enabled, Sollya’s behavior will change as follows:

• When a constant expression is given at the Sollya prompt, Sollya will first try to simplify the expression to a rational number. If such an evaluation to a rational number is possible, Sollya will display that number as an integer or a fraction of two integers. Only if Sollya is not able to simplify the constant expression to a rational number, it will launch the default behavior of evaluating constant expressions to floating-point numbers that are generally faithful roundings of the expressions.

• When the global mode autosimplify is on, which is the default, Sollya will additionally use rational arithmetic while trying to simplify expressions given in argument of commands.
Even when rationalmode is on, Sollya will not be able to exhibit integer ratios between transcendental quantities. For example, Sollya will not display \( \frac{1}{6} \) for \( \arcsin \left( \frac{1}{2} \right) / \pi \) but 0.16666.... Sollya’s evaluator for rational arithmetic is only able to simplify rational expressions based on addition, subtraction, multiplication, division, negation, perfect squares (for square root) and integer powers.

The following example illustrates what can and what cannot be done with Sollya’s mode for rational arithmetic:

```
> 1/3 - 1/7;
Warning: rounding has happened. The value displayed is a faithful rounding to 16
5 bits of the true result.
0.19047619047619047619047619047619047619047619047619
> rationalmode = on;
Rational mode has been activated.
> 1/3 - 1/7;
4 / 21
> (2 + 1/7)^2 + (6/7)^2 + 2 * (2 + 1/7) * 6/7;
9
> rationalmode = off;
Rational mode has been deactivated.
> (2 + 1/7)^2 + (6/7)^2 + 2 * (2 + 1/7) * 6/7;
Warning: rounding has happened. The value displayed is a faithful rounding to 16
5 bits of the true result.
9
> rationalmode = on;
Rational mode has been activated.
> asin(1)/pi;
Warning: rounding has happened. The value displayed is a faithful rounding to 16
5 bits of the true result.
0.5
> sin(1/6 * pi);
Warning: rounding has happened. The value displayed is a faithful rounding to 16
5 bits of the true result.
0.5
> exp(1/7 - 3/21) / 7;
Warning: rounding has happened. The value displayed is a faithful rounding to 16
5 bits of the true result.
0.142857142857142857142857142857142857142857142857145
> rationalmode = off;
Rational mode has been deactivated.
> exp(1/7 - 3/21) / 7;
Warning: rounding has happened. The value displayed is a faithful rounding to 16
5 bits of the true result.
0.142857142857142857142857142857142857142857142857145
> print(1/7 - 3/21);
1 / 7 - 3 / 21
> rationalmode = on;
Rational mode has been activated.
> print(1/7 - 3/21);
0
```

### 5.4 Intervals and interval arithmetic

Sollya can manipulate intervals that are closed subsets of the real numbers. Several ways of defining intervals exist in Sollya. There is the most common way where intervals are composed of two numbers or constant expressions representing the lower and the upper bound. These values are separated either by commas or semi-colons. Interval bound evaluation is performed in a way that ensures the inclusion
property: all points in the original, unevaluated interval will be contained in the interval with its bounds evaluated to floating-point numbers.

```
> d=[1;2];
> d2=[1,1+1];
> d==d2;
true
> prec=12!;
> 8095.1;
Warning: Rounding occurred when converting the constant "8095.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
8096
> [8095.1; 8096.1];
Warning: Rounding occurred when converting the constant "8095.1" to floating-point with 12 bits.
The inclusion property is nevertheless satisfied.
Warning: Rounding occurred when converting the constant "8096.1" to floating-point with 12 bits.
The inclusion property is nevertheless satisfied.
[8094;8098]
```

Sollya has a mode for printing intervals that are that thin that their bounds have a number of decimal digits in common when printed. That mode is called midpointmode; see below for an introduction and section 8.105 for details. As Sollya must be able to parse back its own output, a syntax is provided to input intervals in midpoint mode. However, please pay attention to the fact that the notation used in midpoint mode generally increases the width of intervals: hence when an interval is displayed in midpoint mode and read again, the resulting interval may be wider than the original interval.

```
> midpointmode = on!;
> [1.725e4;1.75e4];
0.17~2/5~e5
> 0.17~2/5~e5;
0.17~2/5~e5
> midpointmode = off!;
> 0.17~2/5~e5;
[17200;17500]
```

In some cases, intervals become infinitely thin in theory, in which case one tends to think of point intervals even if their floating-point representation is not infinitely thin. Sollya provides a very convenient way for input of such point intervals. Instead of writing [a;a], it is possible to just write [a]. Sollya will expand the notation while making sure that the inclusion property is satisfied:

```
> [3];
[3;3]
> [1/7];
Warning: the given expression is not a constant but an expression to evaluate. A faithful evaluation to 29 bits will be used.
[0.14285713;0.142857149]
> [exp(8)];
Warning: the given expression is not a constant but an expression to evaluate. A faithful evaluation to 29 bits will be used.
[2.980957e3;2.980958e3]
```

When the mode midpointmode is set to on (see 8.105, Sollya will display intervals that are provably reduced to one point in this extended interval syntax. It will use midpointmode syntax for intervals that are sufficiently thin but not reduced to one point (see section 8.105 for details):
Sollya intervals are internally represented with floating-point numbers as bounds; rational numbers are not supported here. If bounds are defined by constant expressions, these are evaluated to floating-point numbers using the current precision. Numbers or variables containing numbers keep their precision for the interval bounds.

Constant expressions get evaluated to floating-point values immediately; this includes \( \pi \) and rational numbers, even when `rationalmode` is on (see section 5.3 for this mode).

You can get the upper-bound (respectively the lower-bound) of an interval with the command `sup` (respectively `inf`). The middle of the interval can be computed with the command `mid`. Let us also mention that these commands can also be used on numbers (in that case, the number is interpreted as an interval containing only one single point. In that case the commands `inf`, `mid` and `sup` are just the identity):
Let us mention that the `mid` operator never provokes a rounding. It is rewritten as an unevauated expression in terms of `inf` and `sup`.

`Sollya` permits intervals to also have non-real bounds, such as infinities or NaNs. When evaluating certain expressions, in particular given as interval bounds, `Sollya` will itself generate intervals containing infinities or NaNs. When evaluation yields an interval with a NaN bound, the given expression is most likely undefined or numerically unstable. Such results should not be trusted; a warning is displayed.

While computations on intervals with bounds being NaN will always fail, `Sollya` will try to interpret infinities in the common way as limits. However, this is not guaranteed to work, even if it is guaranteed that no unsafe results will be produced. See also section 5.2 for more detail on infinities in `Sollya`. The behavior of interval arithmetic on intervals containing infinities or NaNs is subject to debate; moreover, there is no complete consensus on what should be the result of the evaluation of a function `f` over an interval `I` containing points where `f` is not defined. `Sollya` has its own philosophy regarding these questions. This philosophy is explained in Appendix 9 at the end of this document.
When such expressions involving intervals are given, Sollya will follow the rules of interval arithmetic in precision `prec` for immediately evaluating them to interval enclosures. While Sollya’s evaluator always guarantees the inclusion property, it also applies some optimisations in some cases in order to make the image interval as thin as possible. For example, Sollya will use a Taylor expansion based evaluation if a composed function, call it \( f \), is applied to an interval. In other words, in this case Sollya will behave as if the `evaluate` command (see section 8.55) were implicitly used. In most cases, the result will be different from the one obtained by replacing all occurrences of the free variable of a function by the interval the function is to be evaluated on:

\[
\begin{align*}
> f &= x - \sin(x); \\
> [-1b-10;1b-10] &- \sin([-1b-10;1b-10]); \\
&[-1.95312484477957829894e-3;1.95312484477957829894e-3] \\
> f &= (-1b-10;1b-10)); \\
&[-1.55220421701117626897e-10;1.55220421701117626897e-10] \\
> \text{evaluate}(f, [-1b-10;1b-10]); \\
&[-1.55220421701117626897e-10;1.55220421701117626897e-10]
\end{align*}
\]

5.5 Functions

Sollya knows only about functions with one single variable. The first time in a session that an unbound name is used (without being assigned) it determines the name used to refer to the free variable.

The basic functions available in Sollya are the following:

- `+`, `−`, `*`, `/`, `−`
- `sqrt`
- `abs`
- `sin`, `cos`, `tan`, `sinh`, `cosh`, `tanh`
- `asin`, `acos`, `atan`, `asinh`, `acosh`, `atanh`
- `exp`, `expm1` (defined as `expm1(x) = exp(x) − 1`)
- `log` (natural logarithm), `log2` (binary logarithm), `log10` (decimal logarithm), `log1p` (defined as `log1p(x) = log(1 + x)``
- `erf`, `erfc`
- `halfprecision`, `single`, `double`, `doubleextended`, `doubledouble`, `quad`, `tripledouble` (see sections 8.76, 8.166, 8.47, 8.48, 8.140, and 8.185)
- `HP`, `SG`, `D`, `DE`, `DD`, `QD`, `TD` (see sections 8.76, 8.166, 8.47, 8.48, 8.140, and 8.185)
- `floor`, `ceil`, `nearestint`.

The constant \( π \) is available through the keyword `pi` as a 0-ary function:

\[
\begin{align*}
> \text{display} &= \text{binary}!; \\
> \text{prec} &= 12!; \\
> a &= \text{pi}; \\
> a; \\
\text{Warning}: \text{rounding has happened. The value displayed is a faithful rounding to 12 bits of the true result.} \\
1.10010010001_2 * 2^{-1}
\end{align*}
\]
The reader may wish to see Sections 8.94 and 8.71 for ways of dynamically adding other base functions to Sollya.

5.6 Strings

Anything written between quotes is interpreted as a string. The infix operator \@\@ concatenates two strings. To get the length of a string, use the length function. You can access the \(i\)-th character of a string using brackets (see the example below). There is no character type in Sollya: the \(i\)-th character of a string is returned as a string itself.

```plaintext
> s1 = "Hello "; s2 = "World!";
> s = s1@s2;
> length(s);
12
> s[0];
H
> s[11];
!
```

Strings may contain the following escape sequences: \", \", \?, \?, \n, \t, \a, \b, \f, \r, \v, \x[hexadecimal number] and \[octal number]. Refer to the C99 standard for their meaning.

5.7 Particular values

Sollya knows about some particular values. These values do not really have a type. They can be stored in variables and in lists. A (possibly not exhaustive) list of such values is the following one:

- on, off (see sections 8.117 and 8.116)
- dyadic, powers, binary, decimal, hexadecimal (see sections 8.50, 8.125, 8.18, 8.34 and 8.78)
- file, postscript, postscriptfile (see sections 8.64, 8.125 and 8.126)
- RU, RD, RN, RZ (see sections 8.159, 8.145, 8.154 and 8.160)
- absolute, relative (see sections 8.2 and 8.148)
- floating, fixed (see sections 8.67 and 8.66)
- halfprecision, single, double, doubleextended, doubledouble, quad, tripledouble (see sections 8.76, 8.166, 8.47, 8.49, 8.48, 8.140 and 8.185)
- HP, SG, D, DE, DD, QD, TD (see sections 8.76, 8.166, 8.47, 8.49, 8.48, 8.140 and 8.185)
- perturb (see section 8.120)
- honorcoeffprec (see section 8.79)
- default (see section 8.35)
- error (see section 8.54)
- void (see section 8.190)
5.8 Lists

Objects can be grouped into lists. A list can contain elements with different types. As for strings, you can concatenate two lists with \( \oplus \). The function `length` also gives the length of a list.

You can prepend an element to a list using `:.` and you can append an element to a list using `:`.

The following example illustrates some features:

```plaintext
> L = ["foo" ];
> L = L:.1;
> L = "bar" .:L;
> L;
["bar", "foo", 1]
> L[1];
foo
> L&L;
["bar", "foo", 1, "bar", "foo", 1]
```

Lists can be considered arrays and elements of lists can be referenced using brackets. Possible indices start at 0. The following example illustrates this point:

```plaintext
> L = [1,2,3,4,5];
> L;
[1, 2, 3, 4, 5]
> L[3];
4
```

Lists may contain ellipses indicated by `,...,` between elements that are constant and evaluate to integers that are incrementally ordered. Sollya translates such ellipses to the full list upon evaluation. The use of ellipses between elements that are not constants is not allowed. This feature is provided for ease of programming; remark that the complexity for expanding such lists is high. For illustration, see the following example:

```plaintext
> [1,...,5];
[1, 2, 3, 4, 5]
> [-5,...,5];
[-5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5]
> [3,...,1];
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
> [true,...,false];
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
```

Lists may be continued to infinity by means of the `...` indicator after the last element given. At least one element must explicitly be given. If the last element given is a constant expression that evaluates to an integer, the list is considered as continued to infinity by all integers greater than that last element. If the last element is another object, the list is considered as continued to infinity by re-duplicating this last element. Let us remark that bracket notation is supported for such end-elliptic lists even for implicitly given elements. However, evaluation complexity is high. Combinations of ellipses inside a list and in its end are possible. The usage of lists described here is best illustrated by the following examples:
> L = [[1,2,true,3...]];  
> L;  
[1, 2, true, 3...]
> L[2];  
true  
> L[3];  
3  
> L[4];  
4  
> L[1200];  
1200  
> L = [[1,...,5,true...]];  
> L;  
[1, 2, 3, 4, 5, true...]
> L[1200];  
true

5.9 Structures

In a similar way as in lists, Sollya allows data to be grouped in – untyped – structures. A structure forms an object to which other objects can be added as elements and identified by their names. The elements of a structure can be retrieved under their name and used as usual. The following sequence shows that point:

> s.a = 17;  
> s.b = exp(x);  
> s.a;  
17  
> s.b;  
exp(x)  
> s.b(1);  
Warning: rounding has happened. The value displayed is a faithful rounding to 16 5 bits of the true result.  
2.71828182845904523536028747135266249775724709369998
> s.d.a = [-1;1];  
> s.d.b = sin(x);  
> inf(s.d.a);  
-1  
> diff(s.d.b);  
\cos(x)

Structures can also be defined literally using the syntax illustrated in the next example. They will also be printed in that syntax.
If the variable a is bound to an existing structure, it is possible to use the “dot notation” a.b to assign the value of the field b of the structure a. This works even if b is not yet a field of a: in this case a new field is created inside the structure a.

Besides, the dot notation can be used even when a is unassigned. In this case a new structure is created with a field b, and this structure is bound to a. However, the dot notation cannot be used if a is already bound to something that is not a structure.

These principles apply recursively: for instance, if a is a structure that contains only one field d, the command a.b.c = 3 creates a new field named b inside the structure a; this field itself is a structure containing the field c. The command a.d.c = 3 is allowed if a.d is already a structure, but forbidden otherwise (e.g. if a.d was equal to sin(x)). This is summed up in the following example.

```
> a = { .f = exp(x), .dom = [-1;1] };  
> a; 
{ .f = exp(x), .dom = [-1;1] } 
> a.f; 
exp(x) 
> a.dom; 
[-1;1] 
> b.f = sin(x); 
> b.dom = [-1b-5;1b-5]; 
> b; 
{ .dom = [-3.125e-2;3.125e-2], .f = sin(x) } 
> { .f = asin(x), .dom = [-1;1] }.f(1); 
Warning: rounding has happened. The value displayed is a faithful rounding to 16  
5 bits of the true result. 
1.57079632679489661923132169163975144209858469968754 
```

When printed, the elements of a structure are not sorted in any manner. They get printed in an arbitrary order that just maintains the order given in the definition of literate structures. That said, when compared, two structures compare equal iff they contain the same number of identifiers, with the
same names and iff the elements of corresponding names all compare equal. This means the order does not matter in comparisons and otherwise does only for printing.

The following example illustrates this matter:

```plaintext
> a = { .f = exp(x), .a = -1, .b = 1 };
> a;
{ .f = exp(x), .a = -1, .b = 1 }
> a.info = "My function";
> a;
{ .info = "My function", .f = exp(x), .a = -1, .b = 1 }
> b = { .a = -1, .f = exp(x), .info = "My function", .b = 1 };
> b;
{ .a = -1, .f = exp(x), .info = "My function", .b = 1 }
> a == b;
true
> b.info = "My other function";
> a == b;
false
> b.info = "My function";
> a == b;
true
> b.something = true;
> a == b;
false
```

6 Iterative language elements: assignments, conditional statements and loops

6.1 Blocks

Statements in Sollya can be grouped in blocks, so-called begin-end-blocks. This can be done using the key tokens { and }. Blocks declared this way are considered to be one single statement. As already explained in section 4 using begin-end-blocks also opens the possibility of declaring variables through the keyword var.

6.2 Assignments

Sollya has two different assignment operators, = and :=. The assignment operator = assigns its right-hand-object “as is”, i.e. without evaluating functional expressions. For instance, i = i + 1; will dereference the identifier i with some content, notate it y, build up the expression (function) y + 1 and assign this expression back to i. In the example, if i stood for the value 1000, the statement i = i + 1; would assign “1000 + 1” – and not “1001” – to i. The assignment operator := evaluates constant functional expressions before assigning them. On other expressions it behaves like =. Still in the example, the statement i := i + 1; really assigns 1001 to i.

Both Sollya assignment operators support indexing of lists or strings elements using brackets on the left-hand-side of the assignment operator. The indexed element of the list or string gets replaced by the right-hand-side of the assignment operator. When indexing strings this way, that right-hand side must evaluate to a string of length 1. End-elliptic lists are supported with their usual semantic for this kind of assignment. When referencing and assigning a value in the implicit part of the end-elliptic list, the list gets expanded to the corresponding length.

The following examples well illustrate the behavior of assignment statements:
> autosimplify = off;
Automatic pure tree simplification has been deactivated.
> i = 1000;
> i = i + 1;
> print(i);
1000 + 1
> i := i + 1;
> print(i);
1002
> L = [|1,...,5|];
> print(L);
[|1, 2, 3, 4, 5|]
> print(L);
[|1, 2, 3, 4 + 1, 6|]
> L[5] = true;
> L;
[|1, 2, 3, 5, 6, true|]
> s = "Hello world";
> s;
Hello world
> s[1] = "a";
> s;
Hallo world
> s[2] = "foo";
Warning: the string to be assigned is not of length 1.
This command will have no effect.
> L = [|true,1,...,5,9...|];
> L;
[|true, 1, 2, 3, 4, 5, 9...|]
> L[13] = "Hello";
> L;
[|true, 1, 2, 3, 4, 5, 9, 10, 11, 12, 13, 14, 15, "Hello", 17...|]

The indexing of lists on left-hand sides of assignments is reduced to the first order. Multiple indexing of lists of lists on assignment is not supported for complexity reasons. Multiple indexing is possible in right-hand sides.

> L = [| 1, 2, [|"a", "b", [|true, false|] |] |];
> L[2][2][1];
false
> L[2][2][1] = true;
Warning: the first element of the left-hand side is not an identifier.
This command will have no effect.
> L[2][2] = "c";
Warning: the first element of the left-hand side is not an identifier.
This command will have no effect.
> L[2] = 3;
> L;
[|1, 2, 3|]

6.3 Conditional statements
Sollya supports conditional statements expressed with the keywords if, then and optionally else. Let us mention that only conditional statements are supported and not conditional expressions.
The following examples illustrate both syntax and semantic of conditional statements in Sollya.
Concerning syntax, be aware that there must not be any semicolon before the else keyword.

```
> a = 3;
> b = 4;
> if (a == b) then print("Hello world");
> b = 3;
> if (a == b) then print("Hello world");
Hello world
> if (a == b) then print("You are telling the truth") else print("Liar!");
You are telling the truth
```

### 6.4 Loops
Sollya supports three kinds of loops. General while-condition loops can be expressed using the keywords while and do. One has to be aware of the fact that the condition test is executed always before the loop, there is no do-until-condition loop. Consider the following examples for both syntax and semantic:

```
> verbosity = 0!
> prec = 30!
> i = 5;
> while (expm1(i) > 0) do { expm1(i); i := i - 1; }
1.474131591e2
5.359815e1
1.908553692e1
6.389061
1.718281827
> print(i);
0
```

The second kind of loops are loops on a variable ranging from a numerical start value and a end value. These kind of loops can be expressed using the keywords for, from, to, do and optionally by. The by statement indicates the width of the steps on the variable from the start value to the end value. Once again, syntax and semantic are best explained with an example:

```
> for i from 1 to 5 do print("Hello world",i);
Hello world 1
Hello world 2
Hello world 3
Hello world 4
Hello world 5
> for i from 2 to 1 by -0.5 do print("Hello world",i);
Hello world 2
Hello world 1.5
Hello world 1
```

The third kind of loops are loops on a variable ranging on values contained in a list. In order to ensure the termination of the loop, that list must not be end-elliptic. The loop is expressed using the keywords for, in and do as in the following examples:
\[ L = \{ \text{true, false, 1,...,4, "Hello", exp(x)} \} \]

\[ \text{for i in L do i;} \]
\[ \text{true} \]
\[ \text{false} \]
\[ 1 \]
\[ 2 \]
\[ 3 \]
\[ 4 \]
\[ \text{Hello} \]
\[ \text{exp(x)} \]

For both types of for loops, assigning the loop variable is allowed and possible. When the loop terminates, the loop variable will contain the value that made the loop condition fail. Consider the following examples:

\[ \text{for i from 1 to 5 do \{ if (i == 3) then i = 4 else i; \};} \]
\[ 1 \]
\[ 2 \]
\[ 5 \]
\[ > i; \]
\[ 6 \]

7 Functional language elements: procedures and pattern matching

7.1 Procedures

Sollya has some elements of functional languages. In order to avoid confusion with mathematical functions, the associated programming objects are called procedures in Sollya.

Sollya procedures are common objects that can be, for example, assigned to variables or stored in lists. Procedures are declared by the `proc` keyword; see section \[8.137\] for details. The returned procedure object must then be assigned to a variable. It can hence be applied to arguments with common application syntax. The `procedure` keyword provides an abbreviation for declaring and assigning a procedure; see section \[8.138\] for details.

Sollya procedures can return objects using the `return` keyword at the end of the `begin-end-block` of the procedure. Section \[8.152\] gives details on the usage of `return`. Procedures further can take any type of object in argument, in particular also other procedures that are then applied to arguments. Procedures can be declared inside other procedures.

Common Sollya procedures are declared with a certain number of formal parameters. When the procedure is applied to actual parameters, a check is performed if the right number of actual parameters is given. Then the actual parameters are applied to the formal parameters. In some cases, it is required that the number of parameters of a procedure be variable. Sollya provides support for the case with procedures with an arbitrary number of actual arguments. When the procedure is called, those actual arguments are gathered in a list which is applied to the only formal list parameter of a procedure with an arbitrary number of arguments. See section \[8.138\] for the exact syntax and details; an example is given just below.

Let us remark that declaring a procedure does not involve any evaluation or other interpretation of the procedure body. In particular, this means that constants are evaluated to floating-point values inside Sollya when the procedure is applied to actual parameters and the global precision valid at this moment.

Sollya procedures are well illustrated with the following examples:
> succ = proc(n) { return n + 1; }
> succ(5);
6
> 3 + succ(0);
4
> succ;
proc(n)
{
    nop;
    return (n) + (1);
}

> add = proc(m,n) { var res; res := m + n; return res; }
> add(5,6);
11
> hey = proc() { print("Hello world."); }
> hey();
Hello world.
> print(hey());
Hello world.
void
> hey;
proc()
{
    print("Hello world.");
    return void;
}

> fac = proc(n) { var res; if (n == 0) then res := 1 else res := n * fac(n - 1); return res; }
> fac(5);
120
> fac(11);
39916800
> fac;
proc(n)
{
    var res;
    if (n) == (0) then
        res := 1
    else
        res := (n) * (fac((n) - (1)));
    return res;
}
> sumall = proc(args = ...) { var i, acc; acc = 0; for i in args do acc = acc + i; return acc; }
> sumall;
proc(args = ...)
{
    var i, acc;
    acc = 0;
    for i in args do
        acc = (acc) + (i);
    return acc;
}
> sumall();
0
> sumall(1);
1
> sumall(1,5);
6
> sumall(1,5,9);
15
> sumall @ [|1,5,9,4,8|];
27
>
Let us note that, when writing a procedure, one does not know what will be the name of the free variable at run-time. This is typically the context when one should use the special keyword \_x\_:

> ChebPolynomials = proc(n) {
    var i, res;
    if (n<0) then res = [|||]
    else if (n==0) then res = [|1|]
    else {
        res = [|1, _x_]|;
        for i from 2 to n do res[i] = horner(2*\_x\_*res[i-1]-res[i-2]);
    }
    return res;
}
> f = sin(x);
> T = ChebPolynomials(4);
> canonical = on!;
> for i from 0 to 4 do T[i];
1
x
-1 + 2 * x^-2
-3 * x + 4 * x^-3
1 + -8 * x^-2 + 8 * x^-4

Sollya also supports external procedures, i.e. procedures written in C (or some other language) and dynamically bound to Sollya identifiers. See \ref{8.62} for details.

7.2 Pattern matching

Starting with version 3.0, Sollya supports matching expressions with expression patterns. This feature is important for an extended functional programming style. Further, and most importantly, it allows expression trees to be recursively decomposed using native constructs of the Sollya language. This means no help from external procedures or other compiled-language mechanisms is needed here anymore.
Basically, pattern matching supports relies on one \texttt{Sollya} construct:

\begin{verbatim}
match expr with
  pattern1 : (return-expr1)
  pattern2 : (return-expr2)
  ...
  patternN : (return-exprN)
\end{verbatim}

That construct has the following semantic: try to match the expression \textit{expr} with the patterns \textit{pattern1} through \textit{patternN}, proceeding in natural order. If a pattern \textit{patternI} is found that matches, evaluate the whole \texttt{match ... with} construct to the return expression \textit{return-exprI} associated with the matching pattern \textit{patternI}. If no matching pattern is found, display an error warning and return \texttt{error}. Note that the parentheses around the expressions \textit{return-exprI} are mandatory.

Matching a pattern means the following:

- If a pattern does not contain any programming-language-level variables (different from the free mathematical variable), it matches expressions that are syntactically equal to itself. For instance, the pattern \texttt{exp(sin(3 * x))} will match the expression \texttt{exp(sin(3 * x))}, but it does not match \texttt{exp(sin(x * 3))} because the expressions are not syntactically equal.

- If a pattern does contain variables, it matches an expression \textit{expr} if these variables can be bound to subexpressions of \textit{expr} such that once the pattern is evaluated with that variable binding, it becomes syntactically equal to the expression \textit{expr}. For instance, the pattern \texttt{exp(sin(a * x))} will match the expression \texttt{exp(sin(3 * x))} as it is possible to bind \texttt{a} to \texttt{3} such that \texttt{exp(sin(a * x))} evaluates to \texttt{exp(sin(3 * x))}.

If a pattern \textit{patternI} with variables is matched in a \texttt{match ... with} construct, the variables in the pattern stay bound during the evaluation of the corresponding return expression \textit{return-exprI}. This allows subexpressions to be extracted from expressions and/or recursively handled as needed.

The following examples illustrate the basic principles of pattern matching in \texttt{Sollya}. One can remark that it is useful to use the keyword \_x\_ when one wants to be sure to refer to the free variable in a pattern matching:
As Sollya is not a purely functional language, the match ... with construct can also be used in a more imperative style, which makes it become closer to constructs like switch in C or Perl. In lieu of a simple return expression, a whole block of imperative statements can be given. The expression to be returned by that block is indicated in the end of the block, using the return keyword. That syntax is illustrated in the next example:
> match exp(sin(x)) with
  exp(a) : {
    write("Exponential of ", a, ", \n");
    return a;
  }
  sin(x) : {
    var foo;
    foo = 17;
    write("Sine of x\n");
    return foo;
  }
  default : {
    write("Something else\n");
    bashexecute("LANG=C date");
    return true;
  }
Exponential of sin(x)

sin(x)

> match sin(x) with
  exp(a) : {
    write("Exponential of ", a, ", \n");
    return a;
  }
  sin(x) : {
    var foo;
    foo = 17;
    write("Sine of x\n");
    return foo;
  }
  default : {
    write("Something else\n");
    bashexecute("LANG=C date");
    return true;
  }
Sine of x

17

> match acos(17 * pi * x) with
  exp(a) : {
    write("Exponential of ", a, ", \n");
    return a;
  }
  sin(x) : {
    var foo;
    foo = 17;
    write("Sine of x\n");
    return foo;
  }
  default : {
    write("Something else\n");
    bashexecute("LANG=C date");
    return true;
  }
Something else

Fri Jun 28 18:26:37 CEST 2013

true
In the case when no return statement is indicated for a statement-block in a `match ... with` construct, the construct evaluates to the special value `void` if that pattern matches.

In order to well understand pattern matching in Sollya, it is important to realize the meaning of variables in patterns. This meaning is different from the one usually found for variables. In a pattern, variables are never evaluated to whatever they might have set before the pattern is executed. In contrast, all variables in patterns are new, free variables that will freshly be bound to subexpressions of the matching expression. If a variable of the same name already exists, it will be shadowed during the evaluation of the statement block and the return expression corresponding to the matching expression. This type of semantic implies that patterns can never be computed at run-time, they must always be hard-coded beforehand. However this is necessary to make pattern matching context-free.

As a matter of course, all variables figuring in the expression `expr` to be matched are evaluated before pattern matching is attempted. In fact, `expr` is a usual Sollya expression, not a pattern.

In Sollya, the use of variables in patterns does not need to be linear. This means the same variable might appear twice or more in a pattern. Such a pattern will only match an expression if it contains the same subexpression, associated with the variable, in all places indicated by the variable in the pattern.

The following examples illustrate the use of variables in patterns in detail:

```plaintext
> a = 5;
> b = 6;
> match exp(x + 3) with
   exp(a + b) : {
     print("Exponential");
     print("a = ", a);
     print("b = ", b);
   }
   sin(x) : {
     print("Sine of x");
   }
Exponential
a = x
b = 3
> print("a = ", a, ", b = ", b);
a = 5 , b = 6
>
> a = 5;
> b = 6;
> match exp(x + 3) with
   exp(a + b) : {
     var a, c;
     a = 17;
     c = "Hallo";
     print("Exponential");
     print("a = ", a);
     print("b = ", b);
     print("c = ", c);
   }
   sin(x) : {
     print("Sine of x");
   }
Exponential
a = 17
b = 3
c = Hallo
> print("a = ", a, ", b = ", b);
a = 5 , b = 6
```

36
Pattern matching is meant to be a means to decompose expressions structurally. For this reason and in an analogous way to variables, no evaluation is performed at all on (sub-)expressions that form constant functions. As a consequence, patterns match constant expressions only if they are structurally identical. For example $5 + 1$ only matches $5 + 1$ and not $1 + 5$, $3 + 3$ nor $6$.

This general rule on constant expressions admits one exception. Intervals in Sollya can be defined using constant expressions as bounds. These bounds are immediately evaluated to floating-point constants, though. In order to permit pattern matching on intervals, constant expressions given as bounds of intervals that form patterns are evaluated before pattern matching. However, in order not conflict with the rules of no evaluation of variables, these constant expressions as bounds of intervals in patterns must not contain free variables.
The Sollya keyword `default` has a special meaning in patterns. It acts like a wild-card, matching any (sub-)expression, as long as the whole expression stays correctly typed. Upon matching with `default`, no variable gets bound. This feature is illustrated in the next example:
In Sollya, pattern matching is possible on the following Sollya types and operations defined on them:

- Expressions that define univariate functions, as explained above,
- Intervals with one, two or no bound defined in the pattern by a variable,
- Character sequences, literate or defined using the \texttt{@} operator, possibly with a variable on one of the sides of the \texttt{@} operator,
- Lists, literate, literate with variables or defined using the .: :. and \texttt{@} operators, possibly with a variable on one of the sides of the \texttt{@} operator or one or two variables for .: and :.,
- Structures, literate or literate with variables, and
- All other Sollya objects, matchable with themselves (DE matches DE, on matches on, perturb matches perturb etc.)
Concerning intervals, please pay attention to the fact that expressions involving intervals are immediately evaluated and that structural pattern matching on functions on intervals is not possible. This point is illustrated in the next example:
With respect to pattern matching on lists or character sequences defined using the @ operator, the following is to be mentionned:

- Patterns like a @ b are not allowed as they would need to perform an ambiguous cut of the list or character sequence to be matched. This restriction is maintained even if the variables (here a and b) are constrained by other occurrences in the pattern (for example in a list) which would make the cut unambiguous.

- Recursive use of the @ operator (even mixed with the operators .: and :.) is possible under the condition that there must not exist any other parenthezation of the term in concatenations (@) such that the rule of one single variable for @ above gets violated. For instance, ([| 1 |] @ a) @ (b @ [| 4 |]) is not possible as it can be re-parenthesized [| 1 |] @ (a @ b) @ [| 4 |], which exhibits the ambiguous case.
As mentioned above, pattern matching on Sollya structures is possible. Patterns for such a match are given in a literately, i.e. using the syntax \{ .a = exprA, .b = exprB, \ldots \}. A structure pattern \(sp\) will be matched by a structure \(s\) iff that structure \(s\) contains at least all the elements (like .a, .b etc.) of the structure pattern \(sp\) and iff each of the elements of the structure \(s\) matches the pattern in the corresponding element of the structure pattern \(sp\). The user should be aware of the fact that the structure to be matched is only supposed to have at least the elements of the pattern but that it may contain more elements is a particular Sollya feature. For instance with pattern matching, it is hence possible to ensure that access to particular elements will be possible in a particular code segment. The following example is meant to clarify this point:
8 Commands and functions

8.1 abs

Name: abs
the absolute value.

Library names:
sollya_obj_t sollya_lib_abs(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_abs(sollya_obj_t)
#define SOLLYA_ABS(x) sollya_lib_build_function_abs(x)

Description:
- **abs** is the absolute value function. \(\text{abs}(x) = \begin{cases} x & x > 0 \\ -x & x \leq 0 \end{cases} \).

### 8.2 absolute

Name: **absolute**
- indicates an absolute error for externalplot, fpminimax or supnorm

Library names:
- sollya_obj_t sollya_lib_absolute()
- int sollya_lib_is_absolute(sollya_obj_t)

Usage:
- absolute : absolute\|relative

Description:
- The use of absolute in the command externalplot indicates that during plotting in externalplot an absolute error is to be considered.
  See externalplot for details.
- Used with fpminimax, absolute indicates that fpminimax must try to minimize the absolute error.
  See fpminimax for details.
- When given in argument to supnorm, absolute indicates that an absolute error is to be considered for supremum norm computation.
  See supnorm for details.

Example 1:

```bash
> bashexecute("gcc -fPIC -c externalplotexample.c");
> bashexecute("gcc -shared -o externalplotexample externalplotexample.o -lgmp -lmpfr");
> externalplot("./externalplotexample",absolute,exp(x),[-1/2;1/2],12,perturb);
```

See also: externalplot [8.61], fpminimax [8.69], relative [8.148], bashexecute [8.17], supnorm [8.174]

### 8.3 accurateinfnorm

Name: **accurateinfnorm**
- computes a faithful rounding of the infinity norm of a function

Usage:
- accurateinfnorm(function,range,constant) : (function, range, constant) → constant
- accurateinfnorm(function,range,constant,exclusion range 1,...,exclusion range n) : (function, range, constant, range, ..., range) → constant

Parameters:
- **function** represents the function whose infinity norm is to be computed
- **range** represents the infinity norm is to be considered on
• **constant** represents the number of bits in the significant of the result

• **exclusion range 1** through **exclusion range n** represent ranges to be excluded

Description:

• The command **accurateinfnorm** computes an upper bound to the infinity norm of function **function** in **range**. This upper bound is the least floating-point number greater than the value of the infinity norm that lies in the set of dyadic floating point numbers having **constant** significant mantissa bits. This means the value **accurateinfnorm** evaluates to is at the time an upper bound and a faithful rounding to **constant** bits of the infinity norm of function **function** on range **range**.

If given, the fourth and further arguments of the command **accurateinfnorm**, **exclusion range 1** through **exclusion range n** the infinity norm of the function **function** is not to be considered on.

• The command **accurateinfnorm** is now considered DEPRECATED in Sollya. Users should be aware about the fact that the algorithm behind **accurateinfnorm** is highly inefficient and that other, better suited algorithms, such as **supnorm**, are available inside Sollya. As a matter of fact, while **accurateinfnorm** is maintained for compatibility reasons with legacy Sollya codes, users are advised to avoid using **accurateinfnorm** in new Sollya scripts and to replace it, where possible, by the **supnorm** command.

Example 1:

```plaintext
> p = remez(exp(x), 5, [-1;1]);
> accurateinfnorm(p - exp(x), [-1;1], 20);
4.5205246569216251373291015625e-5
> accurateinfnorm(p - exp(x), [-1;1], 30);
4.520513970358879305422306060591015625e-5
> accurateinfnorm(p - exp(x), [-1;1], 40);
4.52051396713923253400935209356248378753662109375e-5
```

Example 2:

```plaintext
> p = remez(exp(x), 5, [-1;1]);
> midpointmode = on!;
> infnorm(p - exp(x), [-1;1]);
0.45205^5/7^e-4
> accurateinfnorm(p - exp(x), [-1;1], 40);
4.52051396713923253400935209356248378753662109375e-5
```

See also: **infnorm** (8.87), **dirtyinfnorm** (8.42), **supnorm** (8.174), **checkinfnorm** (8.24), **remez** (8.149), **diam** (8.38)

### 8.4 acos

Name: **acos**

the arccosine function.

Library names:

```plaintext
sollya_obj_t sollya_lib_acos(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_acos(sollya_obj_t)
#define SOLLYA_ACOS(x) sollya_lib_build_function_acos(x)
```

Description:

• **acos** is the inverse of the function **cos**: **acos(y)** is the unique number **x** ∈ [0; π] such that **cos(x)***=** y.

• It is defined only for **y** ∈ [-1; 1].

See also: **cos** (8.29)
8.5 acosh

Name: acosh
the arg-hyperbolic cosine function.

Library names:
sollya_obj_t sollya_lib_acosh(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_acosh(sollya_obj_t)
#define SOLLYA_ACOSH(x) sollya_lib_build_function_acosh(x)

Description:
• acosh is the inverse of the function cosh: acosh(y) is the unique number \(x \in [0; +\infty]\) such that \(\cosh(x)=y\).
• It is defined only for \(y \in [0; +\infty]\).

See also: cosh 8.30

8.6 &&

Name: &&
boolean AND operator

Library name:
sollya_obj_t sollya_lib_and(sollya_obj_t, sollya_obj_t)

Usage:
\[
expr1 && expr2 : (boolean, boolean) \rightarrow boolean
\]

Parameters:
• expr1 and expr2 represent boolean expressions

Description:
• && evaluates to the boolean AND of the two boolean expressions expr1 and expr2. && evaluates to true iff both expr1 and expr2 evaluate to true.

Example 1:
\[
> \text{true} \&\& \text{false}; \\
\text{false}
\]

Example 2:
\[
> (1 == \text{exp}(0)) \&\& (0 == \text{log}(1)); \\
\text{true}
\]

See also: || (8.118), ! (8.112)

8.7 :

Name: :
add an element at the end of a list.

Library name:
sollya_obj_t sollya_lib_append(sollya_obj_t, sollya_obj_t)

Usage:
\[
L:x : (list, any type) \rightarrow list
\]
Parameters:

- L is a list (possibly empty).
- x is an object of any type.

Description:

- :: adds the element x at the end of the list L.
- Note that since x may be of any type, it can in particular be a list.

Example 1:

```
> [1,2,3,4]:.5;
[1, 2, 3, 4, 5]
```

Example 2:

```
> [1,2,3]:[4,5,6];
[1, 2, 3, [4, 5, 6]]
```

Example 3:

```
> [[]]:.1;
[1]
```

See also: :: (8.131), @ (8.27)

8.8 ~

Name: ~

floating-point evaluation of a constant expression

Library name:

```
sollya_obj_t sollya_lib_approx(sollya_obj_t)
```

Usage:

```
~ expression : function → constant
~ something : any type → any type
```

Parameters:

- expression stands for an expression that is a constant
- something stands for some language element that is not a constant expression

Description:

- ~ expression evaluates the expression that is a constant term to a floating-point constant. The evaluation may involve a rounding. If expression is not a constant, the evaluated constant is a faithful rounding of expression with precision bits, unless the expression is exactly 0 as a result of cancellation. In the latter case, a floating-point approximation of some (unknown) accuracy is returned.

- ~ does not do anything on all language elements that are not a constant expression. In other words, it behaves like the identity function on any type that is not a constant expression. It can hence be used in any place where one wants to be sure that expressions are simplified using floating-point computations to constants of a known precision, regardless of the type of actual language elements.

- ~ error evaluates to error and provokes a warning.
• \texttt{\~} is a prefix operator not requiring parentheses. Its precedence is the same as for the unary \texttt{+} and \texttt{−} operators. It cannot be repeatedly used without brackets.

Example 1:

\begin{verbatim}
> print(exp(5));
exp(5)
> print(~ exp(5));
1.4841315910257660342115580040552279623487667593878e2
\end{verbatim}

Example 2:

\begin{verbatim}
> autosimplify = off!;
\end{verbatim}

Example 3:

\begin{verbatim}
> print(~sin(5 * pi));
0
\end{verbatim}

Example 4:

\begin{verbatim}
> print(~exp(x));
ex(x)
> print(~ "Hello");
Hello
\end{verbatim}

Example 5:

\begin{verbatim}
> print(~exp(x*5*Pi));
ex((pi) * 5 * x)
> print(exp(x* ~(5*Pi)));
ex(x * 1.57079632679489661923132169163975144209858469968757e1)
\end{verbatim}

Example 6:

\begin{verbatim}
> print(~exp(5)*x);
1.4841315910257660342115580040552279623487667593878e2 * x
> print(~exp(5)*x);
1.4841315910257660342115580040552279623487667593878e2 * x
> print(~(exp(5)*x));
ex(5) * x
\end{verbatim}

See also: \texttt{evaluate (8.55)}, \texttt{prec (8.129)}, \texttt{error (8.54)}

### 8.9 asciiplot

**Name:** \texttt{asciiplot}

plots a function in a range using ASCII characters

**Library name:**

\texttt{void sollya\_lib\_asciiplot(sollya\_obj\_t, sollya\_obj\_t)}

**Usage:**

\texttt{asciiplot(function, range) : (function, range) → void}

**Parameters:**

- \texttt{function} represents a function to be plotted
- range represents a range the function is to be plotted in

Description:

- asciiplot plots the function function in range range using ASCII characters. On systems that provide the necessary TIOCGWINSZ ioctl, Sollya determines the size of the terminal for the plot size if connected to a terminal. If it is not connected to a terminal or if the test is not possible, the plot is of fixed size 77 × 25 characters. The function is evaluated on a number of points equal to the number of columns available. Its value is rounded to the next integer in the range of lines available. A letter x is written at this place. If zero is in the hull of the image domain of the function, an x-axis is displayed. If zero is in range, a y-axis is displayed. If the function is constant or if the range is reduced to one point, the function is evaluated to a constant and the constant is displayed instead of a plot.

Example 1:

> asciiplot(exp(x),[1;2]);

Example 2:
Example 3:

```plaintext
> asciiplot(5,[-1;1]);
5
```

Example 4:

```plaintext
> asciiplot(exp(x),[1;1]);
2.7182818284590452353602874713526624977572709369998
```

See also: plot [8.122], externalplot [8.61]

### 8.10 asin

**Name:** asin

the arcsine function.

**Library names:**

```plaintext
sollya_obj_t sollya_lib_asin(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_asin(sollya_obj_t)
#define SOLLYA_ASIN(x) sollya_lib_build_function_asin(x)
```

**Description:**

- **asin** is the inverse of the function sin: asin(y) is the unique number \( x \in [-\pi/2; \pi/2] \) such that sin\( (x) = y \).
- It is defined only for \( y \in [-1;1] \).

See also: sin [8.165]
8.11 asinh

Name: asinh
the arg-hyperbolic sine function.

Library names:
- `sollya_obj_t sollya_lib_asinh(sollya_obj_t)`
- `sollya_obj_t sollya_lib_build_function_asinh(sollya_obj_t)`
- `#define SOLLYA_ASINH(x) sollya_lib_build_function_asinh(x)`

Description:
- **asinh** is the inverse of the function **sinh**: **asinh**(y) is the unique number x ∈ [−∞; +∞] such that sinhx=y.
- It is defined for every real number y.

See also: **sinh** (8.167)

8.12 atan

Name: atan
the arctangent function.

Library names:
- `sollya_obj_t sollya_lib_atan(sollya_obj_t)`
- `sollya_obj_t sollya_lib_build_function_atan(sollya_obj_t)`
- `#define SOLLYA_ATAN(x) sollya_lib_build_function_atan(x)`

Description:
- **atan** is the inverse of the function **tan**: **atan**(y) is the unique number x ∈ [−π/2; +π/2] such that tanx=y.
- It is defined for every real number y.

See also: **tan** (8.177)

8.13 atanh

Name: atanh
the hyperbolic arctangent function.

Library names:
- `sollya_obj_t sollya_lib_atanh(sollya_obj_t)`
- `sollya_obj_t sollya_lib_build_function_atanh(sollya_obj_t)`
- `#define SOLLYA_ATANH(x) sollya_lib_build_function_atanh(x)`

Description:
- **atanh** is the inverse of the function **tanh**: **atanh**(y) is the unique number x ∈ [−∞; +∞] such that tanhx=y.
- It is defined only for y ∈ [−1; 1].

See also: **tanh** (8.178)

8.14 autodiff

Name: autodiff
Computes the first n derivatives of a function at a point or over an interval.

Library name:
- `sollya_obj_t sollya_lib_autodiff(sollya_obj_t, sollya_obj_t, sollya_obj_t)`

Usage:
**autodiff**(*f*, *n*, *x₀*) : (function, integer, constant) → list
**autodiff**(*f*, *n*, *I*) : (function, integer, range) → list

**Parameters:**
- *f* is the function to be differentiated.
- *n* is the order of differentiation.
- *x₀* is the point at which the function is differentiated.
- *I* is the interval over which the function is differentiated.

**Description:**
- **autodiff** computes the first *n* derivatives of *f* at point *x₀*. The computation is performed numerically, without symbolically differentiating the expression of *f*. Yet, the computation is safe since small interval enclosures are produced. More precisely, **autodiff** returns a list \([f₀, \ldots, fₙ]\) such that, for each *i*, \(fᵢ\) is a small interval enclosing the exact value of \(f^{(i)}(x₀)\).
- Since it does not perform any symbolic differentiation, **autodiff** is much more efficient than **diff** and should be prefered when only numerical values are necessary.
- If an interval *I* is provided instead of a point *x₀*, the list returned by **autodiff** satisfies: \(∀i, f^{(i)}(I) ⊆ fᵢ\). A particular use is when one wants to know the successive derivatives of a function at a non representable point such as \(π\). In this case, it suffices to call **autodiff** with the (almost) point interval \(I = [π]\).
- When *I* is almost a point interval, the returned enclosures \(fᵢ\) are also almost point intervals. However, when the interval *I* begins to be fairly large, the enclosures can be deeply overestimated due to the dependency phenomenon present with interval arithmetic.
- As a particular case, \(f₀\) is an enclosure of the image of *f* over *I*. However, since the algorithm is not specially designed for this purpose it is not very efficient for this particular task. In particular, it is not able to return a finite enclosure for functions with removable singularities (e.g. \(sin(x)/x\) at 0). The command **evaluate** is much more efficient for computing an accurate enclosure of the image of a function over an interval.

**Example 1:**
```plaintext
> L = autodiff(exp(cos(x))+sin(exp(x)), 5, 0);
> midpointmode = on!
> for fᵢ in L do fᵢ;
0.3559752813266941742012789792982961497379810154498~2/4~e1
0.5403023058681397174009366074429766037323104206179~0/3~
-0.301945050739880202461185318553998489364799733880~6/2~e1
-0.2524412954423689519957506964808969886768918239~6/4~e1

9722578623531405568431279949]

Example 3:

> L = autodiff(sin(x)/x, 0, [-1,1]);
> L[0];
[-@Inf@;@Inf@]
> evaluate(sin(x)/x, [-1,1]);
[0.5403023058681397174009366074429766037323104206179;1]

See also: diff\textsuperscript{(8.40)}, evaluate\textsuperscript{(8.55)}

### 8.15 autosimplify

**Name:** autosimplify

activates, deactivates or inspects the value of the automatic simplification state variable

**Library names:**

- void sollya\_lib\_set\_autosimplify\_and\_print(sollya\_obj\_t)
- void sollya\_lib\_set\_autosimplify(sollya\_obj\_t)
- sollya\_obj\_t sollya\_lib\_get\_autosimplify()

**Usage:**

\[
\text{autosimplify} = \text{activation value : on|off} \rightarrow \text{void} \\
\text{autosimplify} = \text{activation value ! : on|off} \rightarrow \text{void} \\
\text{autosimplify : on|off}
\]

**Parameters:**

- \text{activation value} represents \text{on} or \text{off}, i.e. activation or deactivation

**Description:**

- An assignment \text{autosimplify} = \text{activation value}, where \text{activation value} is one of \text{on} or \text{off}, activates respectively deactivates the automatic safe simplification of expressions of functions generated by the evaluation of commands or in argument of other commands.

Sollya commands like remez, taylor or rationalapprox sometimes produce expressions that can be simplified. Constant subexpressions can be evaluated to dyadic floating-point numbers, monomials with coefficients 0 can be eliminated. Further, expressions indicated by the user perform better in many commands when simplified before being passed in argument to a command. When the automatic simplification of expressions is activated, Sollya automatically performs a safe (not value changing) simplification process on such expressions.

The automatic generation of subexpressions can be annoying, in particular if it takes too much time for not enough benefit. Further the user might want to inspect the structure of the expression tree returned by a command. In this case, the automatic simplification should be deactivated.
If the assignment `autosimplify = activation value` is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

Example 1:

```plaintext
> autosimplify = on !;
> print(x - x);
0
> autosimplify = off ;
Automatic pure tree simplification has been deactivated.
> print(x - x);
```

Example 2:

```plaintext
> autosimplify = on !;
> print(rationalapprox(sin(pi/5.9),7));
33 / 65
> autosimplify = off !;
> print(rationalapprox(sin(pi/5.9),7));
33 / 65
```

See also: `print` (8.132), `prec` (8.129), `points` (8.124), `diam` (8.38), `display` (8.45), `verbosity` (8.189), `canonical` (8.21), `taylorrecursions` (8.181), `timing` (8.184), `fullparentheses` (8.70), `midpointmode` (8.105), `hopitalrecursions` (8.80), `remez` (8.149), `rationalapprox` (8.143), `taylor` (8.179)

### 8.16 bashevaluate

**Name:** bashevaluate  
executes a shell command and returns its output as a string

**Library names:**  
sollya_obj_t sollya_lib_bashevaluate(sollya_obj_t, ...)
sollya_obj_t sollya_lib_v_bashevaluate(sollya_obj_t, va_list)

**Usage:**

```plaintext
bashevaluate(command) : string → string
bashevaluate(command,input) : (string, string) → string
```

**Parameters:**

- `command` is a command to be interpreted by the shell.
- `input` is an optional character sequence to be fed to the command.

**Description:**

- `bashevaluate(command)` will execute the shell command `command` in a shell. All output on the command’s standard output is collected and returned as a character sequence.

- If an additional argument `input` is given in a call to `bashevaluate(command,input)`, this character sequence is written to the standard input of the command `command` that gets executed.

- All characters output by `command` are included in the character sequence to which `bashevaluate` evaluates but two exceptions. Every NULL character (‘\0’) in the output is replaced with ‘?’ as Sollya is unable to handle character sequences containing that character. Additionally, if the output ends in a newline character (‘\n’), this character is stripped off. Other newline characters which are not at the end of the output are left as such.

54
Example 1:

```bash
$ bashevaluate("LANG=C date");
Mon Oct 14 12:00:47 CEST 2013
```

Example 2:

```bash
$ [ | bashevaluate("echo Hello") | ];
[|"Hello"|]
```

Example 3:

```bash
$ a = bashevaluate("sed -e 's/a/e/g;','", "Hallo");
$ a;
Hello
```

See also: bashexecute (8.17)

### 8.17 bashexecute

**Name:** bashexecute

executes a shell command.

**Library name:**

void sollya_lib_bashexecute(sollya_obj_t)

**Usage:**

```c
bashexecute(command) : string → void
```

**Parameters:**

- `command` is a command to be interpreted by the shell.

**Description:**

- `bashexecute(command)` lets the shell interpret `command`. It is useful to execute some external code within Sollya.
- `bashexecute` does not return anything. It just executes its argument. However, if `command` produces an output in a file, this result can be imported in Sollya with help of commands like `execute`, `readfile` and `parse`.

Example 1:

```bash
$ bashexecute("LANG=C date");
Mon Oct 14 12:00:51 CEST 2013
```

See also: execute (8.56), readfile (8.146), parse (8.119), bashevaluate (8.16)

### 8.18 binary

**Name:** binary

special value for global state display

**Library names:**

- sollya_obj_t sollya_lib_binary()
- int sollya_lib_is_binary(sollya_obj_t)

**Description:**

- `binary` is a special value used for the global state display. If the global state `display` is equal to `binary`, all data will be output in binary notation.
- As any value it can be affected to a variable and stored in lists.

See also: decimal (8.34), dyadic (8.50), powers (8.128), hexadecimal (8.78), display (8.45)
8.19 bind

Name: bind
partially applies a procedure to an argument, returning a procedure with one argument less

Usage:

\[
\text{bind}(\text{proc}, \text{ident}, \text{obj}) : (\text{procedure}, \text{identifier type}, \text{any type}) \rightarrow \text{procedure}
\]

Parameters:

- \(\text{proc}\) is a procedure to be partially applied to an argument
- \(\text{ident}\) is one of the formal arguments of \(\text{proc}\)
- \(\text{obj}\) is any Sollya object \(\text{ident}\) is to be bound to

Description:

- \(\text{bind}\) allows a formal parameter \(\text{ident}\) of a procedure \(\text{proc}\) to be bound to an object \(\text{obj}\), hence \(\text{proc}\) to be partially applied. The result of this curried application, returned by \(\text{bind}\), is a procedure with one argument less. This way, \(\text{bind}\) permits specialization of a generic procedure, parameterized e.g. by a function or range.

- In the case when \(\text{proc}\) does not have a formal parameter named \(\text{ident}\), \(\text{bind}\) prints a warning and returns the procedure \(\text{proc}\) unmodified.

- \(\text{bind}\) always returns a procedure, even if \(\text{proc}\) only has one argument, which gets bound to \(\text{ident}\). In this case, \(\text{bind}\) returns a procedure which does not take any argument. Hence evaluation, which might provoke side effects, is only performed once the procedure gets used.

- \(\text{bind}\) does not work on procedures with an arbitrary number of arguments.

Example 1:

```sollya
> procedure add(X,Y) { return X + Y; };
> succ = bind(add,X,1);
> succ(5);
6
> succ;
proc(Y)
{
  nop;
  return (proc(X, Y)
  {
    nop;
    return (X) + (Y);
  })(1, Y);
}
```

Example 2:
> procedure add(X,Y) { return X + Y; };  
> succ = bind(add,X,1);  
> five = bind(succ,Y,4);  
> five();  
5  
> five;  
proc()  
{  
nop;  
return (proc(Y)  
{  
nop;  
return (proc(X, Y)  
{  
nop;  
return (X) + (Y);  
})(1, Y);  
})(4);  
}  

Example 3:

> verbosity = 1!;  
> procedure add(X,Y) { return X + Y; };  
> foo = bind(add,R,1);  
Warning: the given procedure has no argument named "R". The procedure is return unchanged.  
> foo;  
proc(X, Y)  
{  
nop;  
return (X) + (Y);  
}  

See also: procedure [8.138], proc [8.137], function [8.71], @ [8.27]

8.20 boolean

Name: boolean

keyword representing a boolean type

Usage:

boolean : type type

Description:

- boolean represents the boolean type for declarations of external procedures by means of externalproc.

Remark that in contrast to other indicators, type indicators like boolean cannot be handled outside the externalproc context. In particular, they cannot be assigned to variables.

See also: externalproc [8.62], constant [8.28], function [8.71], integer [8.88], list of [8.96], range [8.142], string [8.170], object [8.115]

8.21 canonical

Name: canonical

brings all polynomial subexpressions of an expression to canonical form or activates, deactivates or
checks canonical form printing

Library names:
void sollya_lib_set_canonical_and_print(sollya_obj_t)
void sollya_lib_set_canonical(sollya_obj_t)
sollya_obj_t sollya_lib_canonical(sollya_obj_t)
sollya_obj_t sollya_lib_get_canonical()

Usage:

\[
\begin{align*}
\text{canonical}(\text{function}) & : \text{function} \rightarrow \text{function} \\
\text{canonical} = \text{activation value} & : \text{on|off} \rightarrow \text{void} \\
\text{canonical} = \text{activation value} ! & : \text{on|off} \rightarrow \text{void}
\end{align*}
\]

Parameters:

- **function** represents the expression to be rewritten in canonical form
- **activation value** represents on or off, i.e. activation or deactivation

Description:

- The command **canonical** rewrites the expression representing the function **function** in a way such that all polynomial subexpressions (or the whole expression itself, if it is a polynomial) are written in canonical form, i.e. as a sum of monomials in the canonical base. The canonical base is the base of the integer powers of the global free variable. The command **canonical** does not endanger the safety of computations even in **Sollya**’s floating-point environment: the function returned is mathematically equal to the function **function**.

- An assignment **canonical** = **activation value**, where **activation value** is one of on or off, activates respectively deactivates the automatic printing of polynomial expressions in canonical form, i.e. as a sum of monomials in the canonical base. If automatic printing in canonical form is deactivated, automatic printing yields to displaying polynomial subexpressions in Horner form.

  If the assignment **canonical** = **activation value** is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

Example 1:

\[
\begin{align*}
> \text{print}(\text{canonical}(1 + x * (x + 3 * x^2))); \\
1 + x^2 + 3 * x^3 \\
> \text{print}(\text{canonical}((x + 1)^7)); \\
1 + 7 * x + 21 * x^2 + 35 * x^3 + 35 * x^4 + 21 * x^5 + 7 * x^6 + x^7
\end{align*}
\]

Example 2:

\[
\begin{align*}
> \text{print}(\text{canonical}(\exp((x + 1)^5) - \log(\arcsin(((x + 2) + x)^4 * (x + 1)) + x))); \\
\exp(1 + 5 * x + 10 * x^2 + 10 * x^3 + 5 * x^4 + x^5) - \log(\arcsin(16 + 80 * x + 160 * x^3 + 80 * x^4 + 16 * x^5) + x)
\end{align*}
\]

Example 3:
> canonical;
off
> (x + 2)^9;
512 + x * (2304 + x * (4608 + x * (5376 + x * (4032 + x * (672 + x *
(144 + x * (18 + x))))))))
> canonical = on;
Canonical automatic printing output has been activated.
> (x + 2)^9;
512 + 2304 * x + 4608 * x^2 + 5376 * x^3 + 4032 * x^4 + 2016 * x^5 + 672 * x^6 +
144 * x^7 + 18 * x^8 + x^9
> canonical;
on
> canonical = off!;
> (x + 2)^9;
512 + x * (2304 + x * (4608 + x * (5376 + x * (4032 + x * (672 + x *
(144 + x * (18 + x))))))))

8.22 ceil
Name: ceil
the usual function ceil.

Library names:
sollya_obj_t sollya_lib.ceil(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_ceil(sollya_obj_t)
#define SOLLYA_CEIL(x) sollya_lib_build_function_ceil(x)

Description:
• ceil is defined as usual: ceil(x) is the smallest integer y such that y ≥ x.
• It is defined for every real number x.

See also: floor, nearestint, round, RU

8.23 chebyshevform
Name: chebyshevform
computes a rigorous polynomial approximation

Library name:
sollya_obj_t sollya_lib_chebyshevform(sollya_obj_t, sollya_obj_t, sollya_obj_t);

Usage:
chebyshevform(f, n, I) : (function, integer, range) → list

Parameters:
• f is the function to be approximated.
• n is the degree of the polynomial that must approximate f.
• I is the interval over which the function is to be approximated. This interval cannot be a point interval, i.e. its endpoints have to be different.

Description:
• **WARNING:** `chebyshevform` is a certified command, not difficult to use but not completely straightforward to use either. In order to be sure to use it correctly, the reader is invited to carefully read this documentation entirely.

• `chebyshevform` computes an approximation polynomial and an interval error bound for a given function $f$.
  More precisely, it returns a list $L = [p, \text{coeffErrors}, \Delta, \text{chebCoeffs}]$ where:
  
  - $p$ is an approximation polynomial of degree $n$ which is roughly speaking a numerical Chebyshev interpolation polynomial of $f$ over $I$ represented in monomial basis.
  
  - coeffErrors is a list of $n + 1$ intervals. Each interval coeffErrors$i$ contains an enclosure of all the errors accumulated when computing the $i$-th coefficient of $p$.
  
  - $\Delta$ is an interval that provides a bound for the approximation error between $p$ and $f$. See details below.
  
  - chebCoeffs is a list of $n + 1$ intervals. These are the interval coefficients obtained for the representation of interpolation polynomial considered in Chebyshev basis. See details below.

• The polynomial $p$ and the bound $\Delta$ are obtained using Chebyshev Models principles.

• More formally, the mathematical property ensured by the algorithm may be stated as follows:
  Using monomial basis representation given by $p$: there exist (small) values $\varepsilon_i \in \text{coeffsErrors}[i]$ such that:
  \[
  \forall x \in I, \exists \delta \in \Delta, f(x) - p(x) = \sum_{i=0}^{n} \varepsilon_i x^i + \delta.
  \]
  Using Chebyshev basis representation given by $\text{chebCoeffs}$: there exist values $\alpha_i \in \text{chebCoeffs}[i]$ such that:
  \[
  \forall x \in I, \exists \delta \in \Delta, f(x) - \sum_{i=0}^{n} \alpha_i T_i(y) = \delta, \text{ where } [a, b] = I, y = (2x - b - a)/(b - a) \text{ and } T_i(y) \text{ is the } i\text{-th Chebyshev polynomial over } [-1, 1].
  \]

• The algorithm does not guarantee that by increasing the degree of the approximation, the remainder bound will become smaller. Moreover, it may even become larger due to the dependency phenomenon present with interval arithmetic. In order to reduce this phenomenon, a possible solution is to split the definition domain $I$ into several smaller intervals.

Example 1:

```plaintext
> TL=chebyshevform(exp(x), 10, [-1,1]);
> p=TL[0];
> Delta=TL[2];
> p; Delta;
1.00000000000000000000000000000000000000000000017 + x * (1.00000000027389819197739534714536267477771151666417 + x * (0.50000000002276754680233268825409736541187042311 + x * (0.166666666619045065616898899342137151053369328144003 + x * (4.166666621144043973187795059515661615696989046437e-2 + x * (8.333336379479285520342051763254576844423981913792e-3 + x * (1.3889914363614809070686210553721677944219976326265e-3 + x * (1.9834277606472142284727329700227389403558111865906e-4 + x * (2.4795772759827788282218067965324267955768146489014e-5 + x * (2.82540334409824772663163700125420195118047008360658e-6 + x * (2.813698333718543135828091163040197490630455923616e-7))))))))))))

### 8.24 checkinfnorm

**Name:** checkinfnorm

checks whether the infinity norm of a function is bounded by a value
Library name:

sollya_obj_t sollya_lib_checkinfnorm(sollya_obj_t, sollya_obj_t, sollya_obj_t)

Usage:

checkinfnorm(function, range, constant) : (function, range, constant) → boolean

Parameters:

- function represents the function whose infinity norm is to be checked
- range represents the infinity norm is to be considered on
- constant represents the upper bound the infinity norm is to be checked to

Description:

- The command checkinfnorm checks whether the infinity norm of the given function function in the range range can be proven (by Sollya) to be less than the given bound bound. This means, if checkinfnorm evaluates to true, the infinity norm has been proven (by Sollya’s interval arithmetic) to be less than the bound. If checkinfnorm evaluates to false, there are two possibilities: either the bound is less than or equal to the infinity norm of the function or the bound is greater than the infinity norm but Sollya could not conclude using its internal interval arithmetic.

checkinfnorm is sensitive to the global variable diam. The smaller diam, the more time Sollya will spend on the evaluation of checkinfnorm in order to prove the bound before returning false although the infinity norm is bounded by the bound. If diam is equal to 0, Sollya will eventually spend infinite time on instances where the given bound bound is less or equal to the infinity norm of the function function in range range. In contrast, with diam being zero, checkinfnorm evaluates to true iff the infinity norm of the function in the range is bounded by the given bound.

Example 1:

```
> checkinfnorm(sin(x),[0;1.75], 1);
true
> checkinfnorm(sin(x),[0;1.75], 1/2); checkinfnorm(sin(x),[0;20/39],1/2);
false
true
```

Example 2:

```
> p = remez(exp(x), 5, [-1;1]);
> b = dirtyinfnorm(p - exp(x), [-1;1]);
> checkinfnorm(p - exp(x), [-1;1], b);
false
> b1 = round(b, 15, RU);
> checkinfnorm(p - exp(x), [-1;1], b1);
true
> b2 = round(b, 25, RU);
> checkinfnorm(p - exp(x), [-1;1], b2);
false
> diam = 1b-20!;
> checkinfnorm(p - exp(x), [-1;1], b2);
true
```

See also: infnorm [8.87], dirtyinfnorm [8.42], supnorm [8.174], accurateinfnorm [8.3], remez [8.149], diam [8.38]
8.25 coeff

Name: coeff

gives the coefficient of degree \( n \) of a polynomial

Library name:

```c
sollya_obj_t sollya_lib_coeff(sollya_obj_t, sollya_obj_t)
```

Usage:

```c
coeff(f, n) : (function, integer) → constant
```

Parameters:

- \( f \) is a function (usually a polynomial).
- \( n \) is an integer

Description:

- If \( f \) is a polynomial, \( \text{coeff}(f, n) \) returns the coefficient of degree \( n \) in \( f \).
- If \( f \) is a function that is not a polynomial, \( \text{coeff}(f, n) \) returns 0.

Example 1:

```c
> coeff((1+x)^5,3);
10
```

Example 2:

```c
> coeff(sin(x),0);
0
```

See also: degree [8.36], roundcoefficients [8.156], subpoly [8.171]

8.26 composepolynomials

Name: composepolynomials

computes an approximation to the composition of two polynomials and bounds the error

Library name:

```c
sollya_obj_t sollya_lib_composepolynomials(sollya_obj_t, sollya_obj_t)
```

Usage:

```c
composepolynomials(p, q) : (function, function) → structure
```

Parameters:

- \( p \) and \( q \) are polynomials

Description:

- Given two polynomials \( p \) and \( q \), \( \text{composepolynomials}(p, q) \) computes an approximation \( r \) to the polynomial \( (p \circ q) \) and bounds the error polynomial \( r - (p \circ q) \) using interval arithmetic.
- \( \text{composepolynomials} \) always returns a structure containing two elements, \text{poly} and \text{radii}. The element \text{poly} is contains the approximate composed polynomial \( r \). The element \text{radii} contains a list of \( n+1 \) intervals \( a_i \) bounding the coefficients of the error polynomial, which is of the same degree \( n \) as is the composed polynomial \( (p \circ q) \). This is, there exist \( \alpha_i \in a_i \) such that

\[
\sum_{i=0}^{n} \alpha_i x^i = r(x) - (p \circ q)(x).
\]
In the case when either of \( p \) or \( q \) is not a polynomial, the \texttt{composepolynomials} behaves like \texttt{substitute} used in a literate structure. The list of intervals bounding the coefficients of the error polynomial is returned empty.

Example 1:

\[
> \texttt{composepolynomials}(1 + 2 \cdot x + 3 \cdot x^2 + 4 \cdot x^3, 5 + 6 \cdot x + 7 \cdot x^2);
{ \ .\text{radii} = \{[0;0], [0;0], [0;0], [0;0], [0;0], [0;0], [0;0]\}, .\text{poly} = 586 + x * (1992 + x * (4592 + x * (6156 + x * (6111 + x * (3528 + x * 1372))))} }
\]

Example 2:

\[
> \texttt{print(composepolynomials}(1/5 * x + \exp(17) + \log(2) \cdot x^2, x^4 + 1/3 * x^2));
{ \ .\text{radii} = \{[-3.58732406867153170156474773322218529607747057120388e-43;3.58732406867153170156474773322218529607747057120388e-43], [0;0], [-2.67276471009219564614053646715148187881519688010505e-51;2.67276471009219564614053646715148187881519688010505e-51], [0;0], [-1.06910588403687825845621458665927515260775204202e-50;1.06910588403687825845621458665927515260775204202e-50], [0;0], [-1.382117680737565169124291737211185503051875040840e-50;2.1382117680737565169124291737211185503051875040840e-50], [0;0], [-2.693147180559945309417232121458176568075500134360259e-50;2.693147180559945309417232121458176568075500134360259e-50], [0;0], [-2.1382117680737565169124291737211185503051875040840e-50;2.1382117680737565169124291737211185503051875040840e-50], [0;0], [-1.382117680737565169124291737211185503051875040840e-50;2.1382117680737565169124291737211185503051875040840e-50], [0;0], [-1.06910588403687825845621458665927515260775204202e-50;1.06910588403687825845621458665927515260775204202e-50]}; .\text{poly} = 2.415495275357529214775345318038582879886875673527228e7 + x^2 * (0.2770163533955494788241369023842148097727792706698 + x^2 * (0.462098120373296729448214140354510433836667562017 + x^2 * 0.693147180559945309417232121458176568075500134360259))}
\]

Example 3:

\[
> \texttt{composepolynomials}(\sin(x), x + x^2);
{ \ .\text{radii} = \{[0;0], [0;0]\}, .\text{poly} = \sin(x * (1 + x)) }\]

See also: \texttt{substitute} \(8.172\)

8.27 \texttt{@}

Name: \texttt{@}

concatenates two lists or strings or applies a list as arguments to a procedure.

Library name:

\texttt{sollya_obj_t sollya_lib_concat(sollya_obj_t, sollya_obj_t)}

Usage:

\[
L1@L2 : (\text{list, list}) \rightarrow \text{list}
string1@string2 : (\text{string, string}) \rightarrow \text{string}
proc@L1 : (\text{procedure, list}) \rightarrow \text{any type}
\]

Parameters:

- \(L1\) and \(L2\) are two lists.
- \(string1\) and \(string2\) are two strings.
- \(proc\) is a procedure.

Description:

- In its first usage form, \texttt{@} concatenates two lists or strings.
In its second usage form, \( \@ \) applies the elements of a list as arguments to a procedure. In the case when \( \text{proc} \) is a procedure with a fixed number of arguments, a check is done if the number of elements in the list corresponds to the number of formal parameters of the procedure. An empty list can therefore applied only to a procedure that does not take any argument. In the case of a procedure with an arbitrary number of arguments, no such check is performed.

Example 1:

\[
> \[|1,\ldots,3|]\@[|7,8,9|]; \\
[1, 2, 3, 7, 8, 9]
\]

Example 2:

\[
> "Hello "@"World!"; \\
Hello World!
\]

Example 3:

\[
> \text{procedure cool}(a,b,c) \{ \\
\quad \text{write}(a,"", b,"", \text{and }"",c,"", \text{are cool guys.}\n\}; \\
> \text{cool} @ \[| "\text{Christoph}, "\text{Mioara}, "\text{Sylvain" |}]; \\
\text{Christoph, Mioara and Sylvain are cool guys.}
\]

Example 4:

\[
> \text{procedure sayhello}() \{ \\
\quad \text{"Hello! how are you?"}; \\
\}; \\
> \text{sayhello}(); \\
\text{Hello! how are you?} \\
> \text{sayhello} @ [||]; \\
\text{Hello! how are you?}
\]

Example 5:

\[
> \text{procedure add}(L = ...) \{ \\
\quad \text{var acc, i;} \\
\quad acc = 0; \\
\quad \text{for i in L do acc = i + acc;} \\
\quad \text{return acc;} \\
\}; \\
> \text{add}(1,2); \\
3 \\
> \text{add}(1,2,3); \\
6 \\
> \text{add} @ [1, 2]; \\
3 \\
> \text{add} @ [1, 2, 3]; \\
6 \\
> \text{add} @ [||]; \\
0
\]

See also: :: (8.131), :: (8.7), procedure (8.138), proc (8.137), bind (8.19)
8.28 constant

Name: constant

Keyword representing a constant type

Usage:

constant : type type

Description:

- constant represents the constant type for declarations of external procedures externalproc.

Remark that in contrast to other indicators, type indicators like constant cannot be handled outside the externalproc context. In particular, they cannot be assigned to variables.

See also: externalproc (8.62), boolean (8.20), function (8.71), integer (8.88), list of (8.96), range (8.142), string (8.170), object (8.115)

8.29 cos

Name: cos

The cosine function.

Library names:
sollya_obj_t sollya_libCos(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_cos(sollya_obj_t)
#define SOLLYA_COS(x) sollya_lib_build_function_cos(x)

Description:

- cos is the usual cosine function.
- It is defined for every real number x.

See also: acos (8.4), sin (8.165), tan (8.177)

8.30 cosh

Name: cosh

The hyperbolic cosine function.

Library names:
sollya_obj_t sollya_libCosh(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_cosh(sollya_obj_t)
#define SOLLYA_COSH(x) sollya_lib_build_function_cosh(x)

Description:

- cosh is the usual hyperbolic function: \(\cosh(x) = \frac{e^x + e^{-x}}{2}\).
- It is defined for every real number x.

See also: acosh (8.5), sinh (8.167), tanh (8.178), exp (8.57)

8.31 D

Name: D

Short form for double

See also: double (8.47)
8.32  DD
Name: DD
  short form for doubledouble
See also: doubledouble 8.48

8.33  DE
Name: DE
  short form for doubleextended
See also: doubleextended 8.49

8.34  decimal
Name: decimal
  special value for global state display
Library names:
  sollya_obj_t sollya_lib_decimal()
  int sollya_lib_is_decimal(sollya_obj_t)
Description:
  • decimal is a special value used for the global state display. If the global state display is equal to decimal, all data will be output in decimal notation.
  As any value it can be affected to a variable and stored in lists.
See also: dyadic 8.50, powers 8.128, hexadecimal 8.78, binary 8.18, display 8.45

8.35  default
Name: default
  default value for some commands.
Library names:
  sollya_obj_t sollya_lib_default()
  int sollya_lib_is_default(sollya_obj_t)
Description:
  • default is a special value and is replaced by something depending on the context where it is used.
  It can often be used as a joker, when you want to specify one of the optional parameters of a command and not the others: set the value of uninteresting parameters to default.
  • Global variables can be reset by affecting them the special value default.
Example 1:

```plaintext
> p = remez(exp(x),5,[0;1],default,1e-5);
> q = remez(exp(x),5,[0;1],1,1e-5);
> p==q;
true
```

Example 2:

```plaintext
> prec;
165
> prec=200;
The precision has been set to 200 bits.
```
8.36 degree

Name: degree

gives the degree of a polynomial.

Library name:

sollya_obj_t sollya_lib_degree(sollya_obj_t)

Usage:

\[ \text{degree}(f) : \text{function} \rightarrow \text{integer} \]

Parameters:

- \( f \) is a function (usually a polynomial).

Description:

- If \( f \) is a polynomial, \( \text{degree}(f) \) returns the degree of \( f \).
- Contrary to the usage, Sollya considers that the degree of the null polynomial is 0.
- If \( f \) is a function that is not a polynomial, \( \text{degree}(f) \) returns -1.

Example 1:

```plaintext
> degree((1+x)*(2+5*x^2));
3
> degree(0);
0
```

Example 2:

```plaintext
> degree(sin(x));
-1
```

See also: coeff [8.25], subpoly [8.171], roundcoefficients [8.156]

8.37 denominator

Name: denominator

gives the denominator of an expression

Library name:

sollya_obj_t sollya_lib_denominator(sollya_obj_t)

Usage:

\[ \text{denominator}(expr) : \text{function} \rightarrow \text{function} \]

Parameters:

- \( expr \) represents an expression

Description:

- If \( expr \) represents a fraction \( expr1/expr2 \), \( \text{denominator}(expr) \) returns the denominator of this fraction, i.e. \( expr2 \).
  - If \( expr \) represents something else, \( \text{denominator}(expr) \) returns 1.

  Note that for all expressions \( expr \), \( \text{numerator}(expr) / \text{denominator}(expr) \) is equal to \( expr \).

Example 1:
Example 2:

```
> denominator(exp(x));
1
```

Example 3:

```
> a = 5/3;
> b = numerator(a)/denominator(a);
> print(a);
5 / 3
> print(b);
5 / 3
```

Example 4:

```
> a = exp(x/3);
> b = numerator(a)/denominator(a);
> print(a);
exp(x / 3)
> print(b);
exp(x / 3)
```

See also: numerator, rationalmode

8.38 diam

Name: diam

parameter used in safe algorithms of Sollya and controlling the maximal length of the involved intervals.

Library names:

```
void sollya_lib_set_diam_and_print(sollya_obj_t)
void sollya_lib_set_diam(sollya_obj_t)
sollya_obj_t sollya_lib_get_diam()
```

Usage:

```
diam = width : constant → void
diam = width ! : constant → void
diam : constant
```

Parameters:

- width represents the maximal relative width of the intervals used

Description:

- **diam** is a global variable. Its value represents the maximal width allowed for intervals involved in safe algorithms of Sollya (namely infnorm, checkinfnorm, accurateinfnorm, integral, findzeros, supnorm).

- More precisely, **diam** is relative to the width of the input interval of the command. For instance, suppose that **diam**=1e-5: if infnorm is called on interval [0, 1], the maximal width of an interval will be 1e-5. But if it is called on interval [0, 1e-3], the maximal width will be 1e-8.

See also: infnorm, checkinfnorm, accurateinfnorm, integral, findzeros, supnorm
8.39 dieonerrormode

Name: dieonerrormode

global variable controlling if Sollya is exited on an error or not.

Library names:

- void sollya_lib_set_dieonerrormode_and_print(sollya_obj_t)
- void sollya_lib_set_dieonerrormode(sollya_obj_t)
- sollya_obj_t sollya_lib_get_dieonerrormode()

Usage:

dieonerrormode = activation value : on|off → void

dieonerrormode = activation value ! : on|off → void

dieonerrormode : on|off

Parameters:

- activation value controls if Sollya is exited on an error or not.

Description:

- dieonerrormode is a global variable. When its value is off, which is the default, Sollya will not exit on any syntax, typing, side-effect errors. These errors will be caught by the tool, even if a memory might be leaked at that point. On evaluation, the error special value will be produced.

- When the value of the dieonerrormode variable is on, Sollya will exit on any syntax, typing, side-effect errors. A warning message will be printed in these cases at appropriate verbosity levels.

Example 1:

```plaintext
> verbosity = 1!;
> dieonerrormode = off;
Die-on-error mode has been deactivated.
> for i from true to false do i + "Salut";
Warning: one of the arguments of the for loop does not evaluate to a constant.
The for loop will not be executed.
> exp(17);
Warning: rounding has happened. The value displayed is a faithful rounding to 16 5 bits of the true result.
2.41549527535752982147754351803858238798675673527224e7
```

Example 2:

```plaintext
> verbosity = 1!;
> dieonerrormode = off!;
> 5 */ 4;
Warning: syntax error, unexpected ".
The last symbol read has been "."
Will skip input until next semicolon after the unexpected token. May leak memory
> exp(17);
Warning: rounding has happened. The value displayed is a faithful rounding to 16 5 bits of the true result.
2.41549527535752982147754351803858238798675673527224e7
```

Example 3:
Example 4:

```plaintext
> verbosity = 1!
> dieonerrormode;
off
> dieonerrormode = on!
> dieonerrormode;
on
> for i from true to false do i + "Salut";
Warning: one of the arguments of the for loop does not evaluate to a constant.
The for loop will not be executed.
Warning: some syntax, typing or side-effect error has occurred.
As the die-on-error mode is activated, the tool will be exited.
```

Example 5:

```plaintext
> verbosity = 0!
> dieonerrormode = on!
> 5 */ 4;
Warning: syntax error, unexpected '/.
The last symbol read has been "/".
Will skip input until next semicolon after the unexpected token. May leak memory.
Warning: some syntax, typing or side-effect error has occurred.
As the die-on-error mode is activated, the tool will be exited.
```

See also: on [8.117], off [8.116], verbosity [8.189], error [8.54]

### 8.40 diff

Name: diff
differentiation operator

Library name:
```plaintext
sollya_obj_t sollya_lib_diff(sollya_obj_t)
```

Usage:
```plaintext
diff(function) : function → function
```

Parameters:
- `function` represents a function

Description:
- `diff(function)` returns the symbolic derivative of the function `function` by the global free variable.

If `function` represents a function symbol that is externally bound to some code by library, the derivative is performed as a symbolic annotation to the returned expression tree.

Example 1:
```plaintext
> diff(sin(x));
cos(x)
```

Example 2:
Example 3:

```plaintext
> diff(x^x);
x^x * (1 + log(x))
```

See also: library (8.94), autodiff (8.14), taylor (8.179), taylorform (8.180)

## 8.41 dirtyfindzeros

**Name:** dirtyfindzeros
gives a list of numerical values listing the zeros of a function on an interval.

**Library name:**
```
sollya_obj_t sollya_lib_dirtyfindzeros(sollya_obj_t, sollya_obj_t)
```

**Usage:**
```
dirtyfindzeros(f,I) : (function, range) → list
```

**Parameters:**
- `f` is a function.
- `I` is an interval.

**Description:**
- `dirtyfindzeros(f,I)` returns a list containing some zeros of `f` in the interval `I`. The values in the list are numerical approximation of the exact zeros. The precision of these approximations is approximately the precision stored in `prec`. If `f` does not have two zeros very close to each other, it can be expected that all zeros are listed. However, some zeros may be forgotten. This command should be considered as a numerical algorithm and should not be used if safety is critical.
- More precisely, the algorithm relies on global variables `prec` and `points` and it performs the following steps: let `n` be the value of variable `points` and `t` be the value of variable `prec`.
  - Evaluate `|f|` at `n` evenly distributed points in the interval `I`. The working precision to be used is automatically chosen in order to ensure that the sign is correct.
  - Whenever `f` changes its sign for two consecutive points, find an approximation `x` of its zero with precision `t` using Newton’s algorithm. The number of steps in Newton’s iteration depends on `t`: the precision of the approximation is supposed to be doubled at each step.
  - Add this value to the list.

**Example 1:**

```plaintext
> dirtyfindzeros(sin(x),[-5;5]);
[[-3.14159265358979323846264338327950288419716939937508, 0, 3.14159265358979323846264338327950288419716939937508]]
```

**Example 2:**

```plaintext
> L1=dirtyfindzeros(x^2*sin(1/x),[0;1]);
> points=1000!;
> L2=dirtyfindzeros(x^2*sin(1/x),[0;1]);
> length(L1); length(L2);
18
25
```

See also: prec (8.129), points (8.124), findzeros (8.65), dirtyinfnorm (8.42), numberroots (8.113)
8.42 dirtyinfnorm

Name: dirtyinfnorm
computes a numerical approximation of the infinity norm of a function on an interval.

Library name:
sollya_obj_t sollya_lib_dirtyinfnorm(sollya_obj_t, sollya_obj_t)

Usage:

dirtyinfnorm(f,I) : (function, range) → constant

Parameters:
• f is a function.
• I is an interval.

Description:
• dirtyinfnorm(f,I) computes an approximation of the infinity norm of the given function f on the interval I, e.g. max_{x \in I} |f(x)|.
• The interval must be bound. If the interval contains one of -Inf or +Inf, the result of dirtyinfnorm is NaN.
• The result of this command depends on the global variables prec and points. Therefore, the returned result is generally a good approximation of the exact infinity norm, with precision prec. However, the result is generally underestimated and should not be used when safety is critical. Use infnorm instead.
• The following algorithm is used: let n be the value of variable points and t be the value of variable prec.
  – Evaluate |f| at n evenly distributed points in the interval I. The evaluation are faithful roundings of the exact results at precision t.
  – Whenever the derivative of f changes its sign for two consecutive points, find an approximation x of its zero with precision t. Then compute a faithful rounding of |f(x)| at precision t.
  – Return the maximum of all computed values.

Example 1:

```
> dirtyinfnorm(sin(x),[-10;10]);
1
```

Example 2:

```
> prec=15!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.45856
> prec=40!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.45828537135
> prec=100!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.45828537136237644438147455024
> prec=200!;
> dirtyinfnorm(exp(cos(x))*sin(x),[0;5]);
1.45828537136237644438147455023841718299214087993682374094153
```

Example 3:

```
> dirtyinfnorm(x^2, [log(0);log(1)]);
@NaN@
```

See also: prec [8.129], points [8.124], infnorm [8.87], checkinfnorm [8.24], supnorm [8.174]
8.43 dirtyintegral

Name: dirtyintegral
computes a numerical approximation of the integral of a function on an interval.

Library name:
sollya_obj_t sollya_lib_dirtyintegral(sollya_obj_t, sollya_obj_t)

Usage:

dirtyintegral(f, I) : (function, range) → constant

Parameters:

• f is a function.
• I is an interval.

Description:

• dirtyintegral(f, I) computes an approximation of the integral of f on I.
• The interval must be bound. If the interval contains one of -Inf or +Inf, the result of dirtyintegral is NaN, even if the integral has a meaning.
• The result of this command depends on the global variables prec and points. The method used is the trapezium rule applied at n evenly distributed points in the interval, where n is the value of global variable points.
• This command computes a numerical approximation of the exact value of the integral. It should not be used if safety is critical. In this case, use command integral instead.
• Warning: this command is currently known to be unsatisfactory. If you really need to compute integrals, think of using an other tool or report a feature request to sylvain.chevillard@ens-lyon.org.

Example 1:

```
> sin(10);
-0.54402111088936981340474766185137728168364301291621
> dirtyintegral(cos(x), [0;10]);
-0.544003049051526298224805882475382036536298356281
> points=2000!;
> dirtyintegral(cos(x), [0;10]);
-0.54401997751158321972222697312583199035995837926892
```

See also: prec (8.129), points (8.124), integral (8.89)

8.44 dirtysimplify

Name: dirtysimplify
simplifies an expression representing a function

Library name:
sollya_obj_t sollya_lib_dirtysimplify(sollya_obj_t)

Usage:

dirtysimplify(function) : function → function

Parameters:

• function represents the expression to be simplified

Description:
• The command **dirtysimplify** simplifies constant subexpressions of the expression given in argument representing the function *function*. Those constant subexpressions are evaluated using floating-point arithmetic with the global precision **prec**.

**Example 1:**

```plaintext
> print(dirtysimplify(sin(pi * x)));  
sin(3.14159265358979323846264338327950288419716939937508 * x)  
> print(dirtysimplify(erf(exp(3) + x * log(4))));  
erf(2.0085536923187677409285296545817178969879078385544e1 + x * 1.3862943611198906188344642429163531361510002687205)
```

**Example 2:**

```plaintext
> prec = 20!;  
> t = erf(0.5);  
> s = dirtysimplify(erf(0.5));  
> prec = 200!;  
> t;  
0.5204998778130465376827466538919645287364515757579637000588058  
> s;  
0.52050018310546875
```

See also: **simplify** (8.164), **autosimplify** (8.15), **prec** (8.129), **evaluate** (8.55), **horner** (8.81), **ratio-nalmode** (8.144)

### 8.45  display

**Name:** display  
sets or inspects the global variable specifying number notation

**Library names:**

- `void sollya_lib_set_display_and_print(sollya_obj_t)`
- `void sollya_lib_set_display(sollya_obj_t)`
- `sollya_obj_t sollya_lib_get_display()`

**Usage:**

```plaintext
display = notation value : decimal|binary|dyadic|powers|hexadecimal → void  
display = notation value ! : decimal|binary|dyadic|powers|hexadecimal → void  
display : decimal|binary|dyadic|powers|hexadecimal
```

**Parameters:**

- **notation value** represents a variable of type `decimal|binary|dyadic|powers|hexadecimal`

**Description:**

- An assignment `display = notation value`, where **notation value** is one of `decimal`, `dyadic`, `powers`, `binary` or `hexadecimal`, activates the corresponding notation for output of values in `print`, `write` or at the Sollya prompt.

If the global notation variable `display` is `decimal`, all numbers will be output in scientific decimal notation. If the global notation variable `display` is `dyadic`, all numbers will be output as dyadic numbers with Gappa notation. If the global notation variable `display` is `powers`, all numbers will be output as dyadic numbers with a notation compatible with Maple and PARI/GP. If the global notation variable `display` is `binary`, all numbers will be output in binary notation. If the global notation variable `display` is `hexadecimal`, all numbers will be output in C99/IEEE754-2008 notation. All output notations can be parsed back by Sollya, inducing no error if the input and output precisions are the same (see **prec**).
If the assignment \texttt{display = notation value} is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

Example 1:

```plaintext
> display = decimal;
Display mode is decimal numbers.
> a = evaluate(sin(pi * x), 0.25);
> a;
0.7071067811865475244008443621048490392843593768847
> display = binary;
Display mode is binary numbers.
> a;
1.01101010000010011111011001111111011001111110101100111011001110110011101011001101
1001000010111110111111111011100110110110110110110110111001100110110011011011101
010011_2 * 2^(-1)
> display = hexadecimal;
Display mode is hexadecimal numbers.
> a;
0xb.504f333f9de6484597d89b3754abe9f1d6f60ba88p-4
> display = dyadic;
Display mode is dyadic numbers.
> a;
33070006991101558613323983488220944360067107133265b-165
> display = powers;
Display mode is dyadic numbers in integer-power-of-2 notation.
> a;
33070006991101558613323983488220944360067107133265 * 2^(-165)
```

See also: \texttt{print} (8.132), \texttt{write} (8.192), \texttt{decimal} (8.34), \texttt{dyadic} (8.50), \texttt{powers} (8.128), \texttt{binary} (8.18), \texttt{hexadecimal} (8.78), \texttt{prec} (8.129)

8.46  \hspace{1cm} /

Name: /  

division function

Library names:

- \texttt{sollya_obj_t sollya_lib_div(sollya_obj_t, sollya_obj_t)}
- \texttt{sollya_obj_t sollya_lib_build_function_div(sollya_obj_t, sollya_obj_t)}
- \#define SOLLYA_DIV(x,y) sollya_lib_build_function_div((x), (y))

Usage:

- \texttt{function1 / function2 : (function, function) → function}
- \texttt{interval1 / interval2 : (range, range) → range}
- \texttt{interval1 / constant : (range, constant) → range}
- \texttt{interval1 / constant : (constant, range) → range}

Parameters:

- \texttt{function1} and \texttt{function2} represent functions
- \texttt{interval1} and \texttt{interval2} represent intervals (ranges)
- \texttt{constant} represents a constant or constant expression

Description:
• \(/\) represents the division (function) on reals. The expression \(\text{function1} / \text{function2}\) stands for the function composed of the division function and the two functions \(\text{function1}\) and \(\text{function2}\), where \(\text{function1}\) is the numerator and \(\text{function2}\) the denominator.

• \(/\) can be used for interval arithmetic on intervals (ranges). \(/\) will evaluate to an interval that safely encompasses all images of the division function with arguments varying in the given intervals. If the intervals given contain points where the division function is not defined, infinities and NaNs will be produced in the output interval. Any combination of intervals with intervals or constants (resp. constant expressions) is supported. However, it is not possible to represent families of functions using an interval as one argument and a function (varying in the free variable) as the other one.

Example 1:

\[
\begin{align*}
> 5 / 2; \\
2.5
\end{align*}
\]

Example 2:

\[
\begin{align*}
> x / 2; \\
x \times 0.5
\end{align*}
\]

Example 3:

\[
\begin{align*}
> x / x; \\
1
\end{align*}
\]

Example 4:

\[
\begin{align*}
> 3 / 0; \\
@\text{NaN}@\n\end{align*}
\]

Example 5:

\[
\begin{align*}
> \text{diff(sin(x)} / \exp(x)); \\
\left(\exp(x) \times \cos(x) - \sin(x) \times \exp(x) \right) / \exp(x)^2
\end{align*}
\]

Example 6:

\[
\begin{align*}
> [1;2] / [3;4]; \\
[0.25;0.66666666666666666666666666666666666666666666666668] \\
> [1;2] / 17; \\

> -13 / [4;17]; \\
[-3.25;-0.76470588235294117647058823529411764705882352941175]
\end{align*}
\]

See also: + \text{[8.123]}, - \text{[8.107]}, * \text{[8.108]}, "(8.127)"

8.47 double

Names: double, D

rounding to the nearest IEEE 754 double (binary64).

Library names:

- \text{sollya\_obj\_t sollya\_lib\_double(sollya\_obj\_t)}
- \text{sollya\_obj\_t sollya\_lib\_double\_obj()}
- \text{int sollya\_lib\_is\_double\_obj(sollya\_obj\_t)}
- \text{sollya\_obj\_t sollya\_lib\_build\_function\_double(sollya\_obj\_t)}
- \#define SOLLYA\_D(x) sollya\_lib\_build\_function\_double(x)

Description:
- **double** is both a function and a constant.

- As a function, it rounds its argument to the nearest IEEE 754 double precision (i.e. IEEE754-2008 binary64) number. Subnormal numbers are supported as well as standard numbers: it is the real rounding described in the standard.

- As a constant, it symbolizes the double precision format. It is used in contexts when a precision format is necessary, e.g. in the commands round, roundcoefficients and implementpoly. See the corresponding help pages for examples.

Example 1:

```plaintext
> display=binary!;
> D(0.1);
1.100110011001100110011001100110011001100110011001101_2 * 2^(-4)
> D(4.17);
1.00001010111000010100011110101110000010100011110111111_2 * 2^(-2)
> D(1.011_2 * 2^(-1073));
1.1_2 * 2^(-1073)
```

See also: halfprecision [8.76], single [8.166], doubleextended [8.49], doubledouble [8.48], quad [8.140], tripledouble [8.185], roundcoefficients [8.156], implementpoly [8.84], round [8.155], printdouble [8.133]

### 8.48 doubledouble

Names: **doubledouble**, **DD** represents a number as the sum of two IEEE doubles.

Library names:
- sollya_obj_t sollya_lib_double_double(sollya_obj_t)
- sollya_obj_t sollya_lib_double_double_obj()
- int sollya_lib_is_double_double_obj(sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_double_double(sollya_obj_t)
- #define SOLLYA_DD(x) sollya_lib_build_function_double_double(x)

Description:

- **doubledouble** is both a function and a constant.

- As a function, it rounds its argument to the nearest number that can be written as the sum of two double precision numbers.

- The algorithm used to compute doubledouble(x) is the following: let \( x_h = \text{double}(x) \) and let \( x_l = \text{double}(x - x_h) \). Return the number \( x_h + x_l \). Note that if the current precision is not sufficient to exactly represent \( x_h + x_l \), a rounding will occur and the result of doubledouble(x) will be useless.

- As a constant, it symbolizes the double-double precision format. It is used in contexts when a precision format is necessary, e.g. in the commands round, roundcoefficients and implementpoly. See the corresponding help pages for examples.

Example 1:

```plaintext
> verbosity=1!;
> a = 1 + 2^(-100);
> DD(a);
1.0000000000000000000000000000000000000000000000000000000000000000000
> prec=501;
> DD(a);
1.0000000000000000000000000000000000000000000000000000000000000000008
```
See also: halfprecision (8.79), single (8.166), double (8.47), doubleextended (8.49), quad (8.140),
tripledouble (8.185), roundcoefficients (8.156), implementpoly (8.84), round (8.155)

8.49 doubleextended

Names: doubleextended, DE
computes the nearest number with 64 bits of mantissa.

Library names:
sollya_obj_t sollya_lib_doubleextended(sollya_obj_t)
sollya_obj_t sollya_lib_doubleextended_obj()
int sollya_lib_is_doubleextended_obj(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_doubleextended(sollya_obj_t)
#define SOLLYA_DE(x) sollya_lib_build_function_doubleextended(x)

Description:
• doubleextended is a function that computes the nearest floating-point number with 64 bits of
mantissa to a given number. Since it is a function, it can be composed with other Sollya functions
such as exp, sin, etc.
• doubleextended now does handle subnormal numbers for a presumed exponent width of the
double-extended format of 15 bits. This means, with respect to rounding, doubleextended be-
haves as a IEEE 754-2008 binary79 with a 64 bit significand (with a hidden bit normal range),
one sign bit and a 15 bit exponent field would behave. This behavior may be different from the
one observed on Intel-based IA32/Intel64 processors (or compatible versions from other vendors).
However it is the one seen on HP/Intel Itanium when the precision specifier is double-extended
and pseudo-denormals are activated.
• Since it is a function and not a command, its behavior is a bit different from the behavior of
round(x,64,RN) even if the result is exactly the same. round(x,64,RN) is immediately evaluated
whereas doubleextended(x) can be composed with other functions (and thus be plotted and so
on).

Example 1:

> display=binary!;
> DE(0.1);
1.100110011001100110011001100110011001100110011001100110011001101_2 * 2^(-4)
> round(0.1,64,RN);
1.100110011001100110011001100110011001100110011001100110011001101_2 * 2^(-4)

Example 2:

> D(2^(-2000));
0
> DE(2^(-2000));
0

Example 3:

> verbosity=1!;
> f = sin(DE(x));
> f(pi);
Warning: rounding has happened. The value displayed is a faithful rounding to 16
5 bits of the true result.
-5.0165576126683320235573270803307570138315616702549e-20
> g = sin(round(x,64,RN));
Warning: at least one of the given expressions or a subexpression is not correct
ly typed
or its evaluation has failed because of some error on a side-effect.
8.50 dyadic

Name: dyadic

special value for global state display

Library names:

sollya_obj_t sollya_lib_dyadic()
int sollya_lib_is_dyadic(sollya_obj_t)

Description:

• dyadic is a special value used for the global state display. If the global state display is equal to dyadic, all data will be output in dyadic notation with numbers displayed in Gappa format.

As any value it can be affected to a variable and stored in lists.

See also: decimal (8.34), powers (8.128), hexadecimal (8.78), binary (8.18), display (8.45)

8.51 ==

Name: ==

equality test operator

Library name:

sollya_obj_t sollya_lib_cmp_equal(sollya_obj_t, sollya_obj_t)

Usage:

expr1 == expr2 : (any type, any type) → boolean

Parameters:

• expr1 and expr2 represent expressions

Description:

• The operator == evaluates to true iff its operands expr1 and expr2 are syntactically equal and different from error or constant expressions that are not constants and that evaluate to the same floating-point number with the global precision prec. The user should be aware of the fact that because of floating-point evaluation, the operator == is not exactly the same as the mathematical equality. Further remark that according to IEEE 754-2008 floating-point rules, which Sollya emulates, floating-point data which are NaN do not compare equal to any other floating-point datum, including NaN.

Example 1:

```plaintext
> "Hello" == "Hello";
true
> "Hello" == "Salut";
false
> "Hello" == 5;
false
> 5 + x == 5 + x;
true
```

Example 2:
> 1 == exp(0);
true
> asin(1) * 2 == pi;
true
> exp(5) == log(4);
false

Example 3:

> sin(pi/6) == 1/4;
false

Example 4:

> prec = 12;
The precision has been set to 12 bits.
> verbosity = 1!;
> 16384.1 == 16385.1;
Warning: Rounding occurred when converting the constant "16384.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
Warning: Rounding occurred when converting the constant "16385.1" to floating-point with 12 bits.
If safe computation is needed, try to increase the precision.
true

Example 5:

> error == error;
false

Example 6:

> a = "Biba";
> b = NaN;
> a == a;
true
> b == b;
false

See also: != (8.110), > (8.74), >= (8.72), <= (8.92), < (8.101), in (8.85), ! (8.112), && (8.6), || (8.118), error (8.54), prec (8.129)

8.52 erf

Name: erf

the error function.

Library names:

sollya_obj_t sollya_lib_erf(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_erf(sollya_obj_t)
#define SOLLYA_ERF(x) sollya_lib_build_function_erf(x)

Description:

- **erf** is the error function defined by:

\[
erf(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.
\]

- It is defined for every real number \(x\).

See also: erfc (8.53), exp (8.57)
8.53  erfc

Name: erfc
the complementary error function.

Library names:
sollya_obj_t sollya_lib_erfc(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_erfc(sollya_obj_t)
#define SOLLYA_ERFC(x) sollya_lib_build_function_erfc(x)

Description:

- erfc is the complementary error function defined by erfc(x) = 1 - erf(x).
- It is defined for every real number x.

See also: erf (8.52)

8.54  error

Name: error
expression representing an input that is wrongly typed or that cannot be executed

Library names:
sollya_obj_t sollya_lib_error()
int sollya_lib_obj_is_error(sollya_obj_t)

Usage:

    error : error

Description:

- The variable error represents an input during the evaluation of which a type or execution error has been detected or is to be detected. Inputs that are syntactically correct but wrongly typed evaluate to error at some stage. Inputs that are correctly typed but containing commands that depend on side-effects that cannot be performed or inputs that are wrongly typed at meta-level (cf. parse), evaluate to error.

Remark that in contrast to all other elements of the Sollya language, error compares neither equal nor unequal to itself. This provides a means of detecting syntax errors inside the Sollya language itself without introducing issues of two different wrongly typed inputs being equal.

Example 1:

> print(5 + "foo");
error

Example 2:

> error;
error

Example 3:

> error == error;
false
> error != error;
false

Example 4:
> correct = 5 + 6;
> incorrect = 5 + "foo";
> correct == correct;
true
> incorrect == incorrect;
false
> errorhappened = !(incorrect == incorrect);
> errorhappened;
true

See also: void [8.190], parse [8.119], == [8.51], != [8.110]

8.55 evaluate

Name: evaluate
    evaluates a function at a constant point or in a range

Library name:
sollya_obj_t sollya_lib_evaluate(sollya_obj_t, sollya_obj_t)

Usage:

    evaluate(function, constant) : (function, constant) → constant | range
    evaluate(function, range) : (function, range) → range
    evaluate(function, function2) : (function, function) → function

Parameters:

• function represents a function
• constant represents a constant point
• range represents a range
• function2 represents a function that is not constant

Description:

• If its second argument is a constant constant, evaluate evaluates its first argument function at
  the point indicated by constant. This evaluation is performed in a way that the result is a faithful
  rounding of the real value of the function at constant to the current global precision. If such a
  faithful rounding is not possible, evaluate returns a range surely encompassing the real value of
  the function function at constant. If even interval evaluation is not possible because the expression
  is undefined or numerically unstable, NaN will be produced.

• If its second argument is a range range, evaluate evaluates its first argument function by interval
  evaluation on this range range. This ensures that the image domain of the function function on
  the preimage domain range is surely enclosed in the returned range.

• In the case when the second argument is a range that is reduced to a single point (such that
  [1; 1] for instance), the evaluation is performed in the same way as when the second argument is
  a constant but it produces a range as a result: evaluate automatically adjusts the precision of
  the intern computations and returns a range that contains at most three floating-point consecutive
  numbers in precision prec. This corresponds to the same accuracy as a faithful rounding of the
  actual result. If such a faithful rounding is not possible, evaluate has the same behavior as in the
  case when the second argument is a constant.

• If its second argument is a function function2 that is not a constant, evaluate replaces all occur-
  rences of the free variable in function function by function function2.

Example 1:
Example 2:

```plaintext
> print(evaluate(sin(pi * x), 2));
[-1.72986452514381269516508615031098129542836767991679e-12715;7.5941198201187963145069564314525661706039084390067e-12716]
```

Example 3:

```plaintext
> print(evaluate(sin(pi * x), [2, 2.25]));
[-5.143390272677254630046998919961912407349224165421e-50;0.70710678118654752440084436210484903928483593768866]
```

Example 4:

```plaintext
> print(evaluate(sin(pi * x), 2 + 0.25 * x));
\sin((\pi) \cdot (2 + 0.25 \cdot x))
```

Example 5:

```plaintext
> print(evaluate(sin(pi * 1/x), 0));
[-1;1]
```

See also: `isevaluable` [8.91]

### 8.56 `execute`

**Name:** `execute`  
executes the content of a file

**Usage:**

```plaintext
execute(filename) : string → void
```

**Parameters:**
- `filename` is a string representing a file name

**Description:**
- `execute` opens the file indicated by `filename`, and executes the sequence of commands it contains. This command is evaluated at execution time: this way you can modify the file `filename` (for instance using `bashexecute`) and execute it just after.
- If `filename` contains a command `execute`, it will be executed recursively.
- If `filename` contains a call to `restart`, it will be neglected.
- If `filename` contains a call to `quit`, the commands following `quit` in `filename` will be neglected.

**Example 1:**

```plaintext
> a=2;
> a;
2
> print("a=1;") > "example.sollya";
> execute("example.sollya");
> a;
1
```
8.57 exp

Name: exp

the exponential function.

Library names:
  sollya_obj_t sollya_lib_exp(sollya_obj_t)
  sollya_obj_t sollya_lib_build_function_exp(sollya_obj_t)
  #define SOLLYA_EXP(x) sollya_lib_build_function_exp(x)

Description:

• exp is the usual exponential function defined as the solution of the ordinary differential equation
  \[ y' = y \text{ with } y(0) = 1. \]

• exp(x) is defined for every real number x.

See also: exp (8.57), log (8.97)

8.58 expand

Name: expand

expands polynomial subexpressions

Library name:
  sollya_obj_t sollya_lib_expand(sollya_obj_t)

Usage:

    expand(function) : function → function

Parameters:

• function represents a function

Description:

• expand(function) expands all polynomial subexpressions in function function as far as possible.
  Factors of sums are multiplied out, power operators with constant positive integer exponents are replaced by multiplications.
Example 1:

```latex
> print(expand(x^3));
\quad x \cdot x \cdot x
```

Example 2:

```latex
> print(expand((x + 2)^3 + 2 * x));
\quad 8 + 12 \cdot x + 6 \cdot x \cdot x + x \cdot x \cdot x + x + 2 \cdot x
```

Example 3:

```latex
> print(expand(exp((x + (x + 3))^5)));
\quad \exp(243 + 405 \cdot x + 270 \cdot x \cdot x + 90 \cdot x \cdot x \cdot x + 15 \cdot x \cdot x \cdot x \cdot x + x \cdot x \cdot x + 405 + 108 \cdot x \cdot 5 \cdot x + 54 \cdot x \cdot x \cdot 5 \cdot x + 12 \cdot x \cdot x \cdot x \cdot 5 \\
\quad \cdot x + x \cdot x \cdot x \cdot x \cdot 5 \cdot x + x \cdot x \cdot 270 + 27 \cdot x \cdot x \cdot x \cdot 10 + 9 \cdot x \cdot x \cdot x \cdot x \\
\quad \cdot x \cdot 10 + x \cdot x \cdot x \cdot x \cdot x \cdot 10 + x \cdot x \cdot x \cdot x \cdot 90 + 6 \cdot x \cdot x \cdot x \cdot x \cdot 10 + x \\
\quad \cdot x \cdot x \cdot x \cdot x \cdot x \cdot 10 + x \cdot x \cdot x \cdot x \cdot 5 \cdot x + 15 \cdot x \cdot x \cdot x \cdot x \cdot x + x \cdot x \cdot x \cdot x \\
\quad \cdot x \cdot x)
```

See also: `dirtysimplify (8.44)`, `simplify (8.164)`, `horner (8.81)`, `coeff (8.25)`, `degree (8.36)`

### 8.59 expm1

**Name:** expm1  
shifted exponential function.

**Library names:**

- `sollya_obj_t sollya_lib_expm1(sollya_obj_t)`
- `sollya_obj_t sollya_lib_build_function_expm1(sollya_obj_t)`
- `#define SOLLYA_EXPM1(x) sollya_lib_build_function_expm1(x)`

**Description:**

- `expm1` is defined by `expm1(x) = \exp(x) - 1`.
- It is defined for every real number `x`.

See also: `exp (8.37)`

### 8.60 exponent

**Name:** exponent  
returns the scaled binary exponent of a number.

**Library name:**

- `sollya_obj_t sollya_lib_exponent(sollya_obj_t)`

**Usage:**

```latex
exponent(x) : constant → integer
```

**Parameters:**

- `x` is a dyadic number.

**Description:**

- `exponent(x)` is by definition 0 if `x` is one of 0, NaN, or Inf.
- If `x` is not zero, it can be uniquely written as `x = m \cdot 2^e` where `m` is an odd integer and `e` is an integer. `exponent(x)` returns `e`.  

85
Example 1:

\[
\begin{align*}
> & a = \text{round}(\Pi, 20, \text{RN}); \\
> & e = \text{exponent}(a); \\
> & e; \\
> & -17 \\
> & m = \text{mantissa}(a); \\
> & a - m \times 2^e; \\
> & 0
\end{align*}
\]

See also: mantissa \(8.102\), precision \(8.130\)

### 8.61 externalplot

**Name:** externalplot

Plots the error of an external code with regard to a function

**Library names:**

- `void sollya_lib_externalplot(sollya_obj_t, sollya_obj_t, sollya_obj_t, ...
- `void sollya_lib_v_externalplot(sollya_obj_t, sollya_obj_t, sollya_obj_t, ...

**Usage:**

- `externalplot(filename, mode, function, range, precision) : (string, absolute|relative, function, range, integer) → void`
- `externalplot(filename, mode, function, range, precision, perturb) : (string, absolute|relative, function, range, integer, perturb) → void`
- `externalplot(filename, mode, function, range, precision, plot mode, result filename) : (string, absolute|relative, function, range, integer, perturb, file|postscript|postscriptfile, string) → void`
- `externalplot(filename, mode, function, range, precision, perturb, plot mode, result filename) : (string, absolute|relative, function, range, integer, perturb, file|postscript|postscriptfile, string) → void`

**Description:**

- The command `externalplot` plots the error of an external function evaluation code sequence implemented in the object file named `filename` with regard to the function `function`. If `mode` evaluates to `absolute`, the difference of both functions is considered as an error function; if `mode` evaluates to `relative`, the difference is divided by the function `function`. The resulting error function is plotted on all floating-point numbers with `precision` significant mantissa bits in the range `range`.

If the sixth argument of the command `externalplot` is given and evaluates to `perturb`, each of the floating-point numbers the function is evaluated at gets perturbed by a random value that is uniformly distributed in \(±1\) ulp around the original `precision` bit floating-point variable.

If a sixth and seventh argument, respectively a seventh and eighth argument in the presence of `perturb` as a sixth argument, are given that evaluate to a variable of type `file|postscript|postscriptfile` respectively to a character sequence of type `string`, `externalplot` will plot (additionally) to a file in the same way as the command `plot` does. See `plot` for details.

The external function evaluation code given in the object file name `filename` is supposed to define a function name `f` as follows (here in C syntax): `void f(mpfr_t rop, mpfr_t op)`. This function is supposed to evaluate `op` with an accuracy corresponding to the precision of `rop` and assign this value to `rop`.

**Example 1:**

\[
\begin{align*}
> & \text{bashexecute("gcc -fPIC -c externalplotexample.c");} \\
> & \text{bashexecute("gcc -shared -o externalplotexample externalplotexample.o -lgmp -l mpfr");} \\
> & \text{externalplot("./externalplotexample",relative,exp(x),[-1/2;1/2],12,perturb);}
\end{align*}
\]
8.62  externalproc

Name:  externalproc

  binds an external code to a Sollya procedure

Usage:

  externalproc(identifier, filename, argumenttype -> resulttype) : (identifier type, string, type type, type type) \rightarrow void

Parameters:

  • identifier represents the identifier the code is to be bound to
  • filename of type string represents the name of the object file where the code of procedure can be found
  • argumenttype represents a definition of the types of the arguments of the Sollya procedure and the external code
  • resulttype represents a definition of the result type of the external code

Description:

  • externalproc allows for binding the Sollya identifier identifier to an external code. After this binding, when Sollya encounters identifier applied to a list of actual parameters, it will evaluate these parameters and call the external code with these parameters. If the external code indicated success, it will receive the result produced by the external code, transform it to Sollya's internal representation and return it.

  In order to allow correct evaluation and typing of the data in parameter and in result to be passed to and received from the external code, externalproc has a third parameter argumenttype -> resulttype. Both argumenttype and resulttype are one of void, constant, function, object, range, integer, string, boolean, list of constant, list of function, list of object, list of range, list of integer, list of string, list of boolean.

  It is worth mentioning that the difference between the data and result type function and the type object is minimal and due to support of legacy Sollya code. Both Sollya functions and Sollya objects are transferred from and to the external procedure thru the C type sollya_obj_t. The difference is that Sollya will check that a certain object is a mathematical function when function is used as a type, and will skip this test if the object type is used. Similarly, Sollya relies on an object produced by the external procedure to be a mathematical function when function is used and will not make this assumption for object.

  If upon a usage of a procedure bound to an external procedure the type of the actual parameters given or its number is not correct, Sollya produces a type error. An external function not applied to arguments represents itself and prints out with its argument and result types.

  The external function is supposed to return an integer indicating success. It returns its result depending on its Sollya result type as follows. Here, the external procedure is assumed to be implemented as a C function.

  - If the Sollya result type is void, the C function has no pointer argument for the result.
  - If the Sollya result type is constant, the first argument of the C function is of C type mpfr_t *, the result is returned by affecting the MPFR variable.
  - If the Sollya result type is function, the first argument of the C function is of C type sollya_obj_t *, the result is returned by affecting the sollya_obj_t variable.
  - If the Sollya result type is object, the first argument of the C function is of C type sollya_obj_t *, the result is returned by affecting the sollya_obj_t variable.
If the Sollya result type is **range**, the first argument of the C function is of C type mpfi_t *, the result is returned by affecting the MPFI variable.

If the Sollya result type is **integer**, the first argument of the C function is of C type int *, the result is returned by affecting the int variable.

If the Sollya result type is **string**, the first argument of the C function is of C type char **, the result is returned by the char * pointed with a new char *.

If the Sollya result type is **boolean**, the first argument of the C function is of C type int *, the result is returned by affecting the int variable with a boolean value.

If the Sollya result type is **list of** type, the first argument of the C function is of a C type depending on the Sollya return type:

- For a list of **constant**: sollya_constant_list_t *
- For a list of **function**: sollya_obj_list_t *
- For a list of **object**: sollya_obj_list_t *
- For a list of **range**: sollya_constant_list_t *
- For a list of **integer**: sollya_int_list_t *
- For a list of **string**: sollya_string_list_t *
- For a list of **boolean**: sollya_boolean_list_t *

The external procedure affects its possible pointer argument if and only if it succeeds. This means, if the function returns an integer indicating failure, it does not leak any memory to the encompassing environment.

The external procedure receives its arguments as follows: If the Sollya argument type is **void**, no argument array is given. Otherwise the C function receives a C void ** argument representing an array of size equal to the arity of the function where each entry (of C type void *) represents a value with a C type depending on the corresponding Sollya type.

- If the Sollya type is **constant**, the void * is to be cast to mpfr_t *.
- If the Sollya type is **function**, the void * is to be cast to sollya_obj_t.
- If the Sollya type is **object**, the void * is to be cast to sollya_obj_t.
- If the Sollya type is **range**, the void * is to be cast to mpfi_t *.
- If the Sollya type is **integer**, the void * is to be cast to int *.
- If the Sollya type is **string**, the void * is to be cast to char *.
- If the Sollya type is **boolean**, the void * is to be cast to int *.
- If the Sollya type is **list of** type, the void * is to be cast to a list of a type depending on the type of the list argument:

  - For a list of **constant**: sollya_constant_list_t
  - For a list of **function**: sollya_obj_list_t
  - For a list of **object**: sollya_obj_list_t
  - For a list of **range**: sollya_interval_list_t
  - For a list of **integer**: sollya_int_list_t
  - For a list of **string**: sollya_string_list_t
  - For a list of **boolean**: sollya_boolean_list_t

The external procedure is not supposed to alter the memory pointed by its array argument void **.

In both directions (argument and result values), empty lists are represented by NULL pointers.

Similarly to internal procedures, externally bounded procedures can be considered to be objects inside Sollya that can be assigned to other variables, stored in list etc.
The dynamic object file whose name is given to externalproc for binding of an external procedure may also define a destructor function int sollya_external_lib_close(void). If Sollya finds such a destructor function in the dynamic object file, it will call that function when closing the dynamic object file again. This happens when Sollya is terminated or when the current Sollya session is restarted using restart. The purpose of the destructor function is to allow the dynamically bound code to free any memory that it might have allocated before Sollya is terminated or restarted. The dynamic object file is not necessarily needed to define a destructor function. This ensure backward compatibility with older Sollya external library function object files. When defined, the destructor function is supposed to return an integer value indicating if an error has happened. Upon success, the destructor functions is to return a zero value, upon error a non-zero value.

Example 1:

```bash
> bashexecute("gcc -fPIC -Wall -c externalprocexample.c");
> bashexecute("gcc -fPIC -shared -o externalprocexample externalprocexample.o");
> externalproc(foo, "./externalprocexample", (integer, integer) -> integer);
> foo;
foo(integer, integer) -> integer
> foo(5, 6);
11
> verbosity = 1!;
> foo();
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
> a = foo;
> a(5,6);
11
```

See also: library (8.94), libraryconstant (8.95), externalplot (8.61), bashexecute (8.17), void (8.190), constant (8.28), function (8.71), range (8.142), integer (8.88), string (8.170), boolean (8.20), list of (8.96), object (8.115)

8.63 false

Name: false
the boolean value representing the false.

Library names:
- sollya_obj_t sollya_lib_false()
- int sollya_lib_is_false(sollya_obj_t)

Description:
- false is the usual boolean value.

Example 1:

```bash
> true && false;
false
> 2<1;
false
```

See also: true (8.180), && (8.6), || (8.118)
8.64  file

Name: file
special value for commands plot and externalplot

Library names:
   sollya_obj_t sollya_lib_file()
   int sollya_lib_is_file(sollya_obj_t)

Description:
• file is a special value used in commands plot and externalplot to save the result of the command in a data file.
• As any value it can be affected to a variable and stored in lists.

Example 1:

```plaintext
> savemode=file;
> name="plotSinCos";
> plot(sin(x),0,cos(x),[-Pi,Pi],savemode, name);
```

See also: externalplot [8.61], plot [8.122], postscript [8.125], postscriptfile [8.126]

8.65  findzeros

Name: findzeros
gives a list of intervals containing all zeros of a function on an interval.

Library name:
   sollya_obj_t sollya_lib_findzeros(sollya_obj_t, sollya_obj_t)

Usage:
findzeros(f,I) : (function, range) → list

Parameters:
• f is a function.
• I is an interval.

Description:
• findzeros(f,I) returns a list of intervals $I_1,\ldots,I_n$ such that, for every zero $z$ of $f$, there exists some $k$ such that $z \in I_k$.
• The list may contain intervals $I_k$ that do not contain any zero of $f$. An interval $I_k$ may contain many zeros of $f$.
• This command is meant for cases when safety is critical. If you want to be sure not to forget any zero, use findzeros. However, if you just want to know numerical values for the zeros of $f$, dirtyfindzeros should be quite satisfactory and a lot faster.
• If $\delta$ denotes the value of global variable diam, the algorithm ensures that for each $k$, $|I_k| \leq \delta \cdot |I|$.
• The algorithm used is basically a bisection algorithm. It is the same algorithm that the one used for infnorm. See the help page of this command for more details. In short, the behavior of the algorithm depends on global variables prec, diam, taylorrecursions and hospitalrecursions.

Example 1:
> findzeros(sin(x),[-5;5]);
[[[-3.14208984375; -3.140869140625], [-1.220703125e-3; 1.220703125e-3], [3.140869140625; 3.14208984375]]]
> diam=1e-10!;
> findzeros(sin(x),[-5;5]);

8.66 fixed

Name: fixed

indicates that fixed-point formats should be used for fpminimax

Library names:
sollya_obj_t sollya_lib_fixed()
int sollya_lib_is_fixed(sollya_obj_t)

Usage:

    fixed : fixed|floating

Description:

• The use of fixed in the command fpminimax indicates that the list of formats given as argument is to be considered to be a list of fixed-point formats. See fpminimax for details.

Example 1:

> fpminimax(cos(x),6,[[32,32,32,32,32,32,32],[1;1],fixed);
0.9999997480772435665130615234375 + x^2 * (-0.49999268693287074565887451171875 + x^2 * (4.16335149202495813369750765625e-2 + x^2 * (-1.338223926723003387451171875e-3)))

See also: fpminimax (8.69), floating (8.67)

8.67 floating

Name: floating

indicates that floating-point formats should be used for fpminimax

Library names:
sollya_obj_t sollya_lib_floating()
int sollya_lib_is_floating(sollya_obj_t)

Usage:

    floating : fixed|floating

Description:

• The use of floating in the command fpminimax indicates that the list of formats given as argument is to be considered to be a list of floating-point formats. See fpminimax for details.

Example 1:

> fpminimax(cos(x),6,[[32,32,32,32,32,32,32],[1;1],fixed);
0.9999997480772435665130615234375 + x^2 * (-0.49999268693287074565887451171875 + x^2 * (4.16335149202495813369750765625e-2 + x^2 * (-1.338223926723003387451171875e-3)))
See also: fpminimax (8.69), fixed (8.66)

8.68  floor

Name: floor
the usual function floor.

Library names:

sollya_obj_t sollya_lib_floor(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_floor(sollya_obj_t)
#define SOLLYA_FLOOR(x) sollya_lib_build_function_floor(x)

Description:
• floor is defined as usual: floor(x) is the greatest integer y such that y ≤ x.
• It is defined for every real number x.

See also: ceil (8.22), nearestint (8.109), round (8.155), RD (8.145)

8.69  fpminimax

Name: fpminimax
computes a good polynomial approximation with fixed-point or floating-point coefficients

Library names:

sollya_obj_t sollya_lib_fpminimax(sollya_obj_t, sollya_obj_t, sollya_obj_t, sollya_obj_t, ...)
sollya_obj_t sollya_lib_v_fpminimax(sollya_obj_t, sollya_obj_t, sollya_obj_t, sollya_obj_t, va_list)

Usage:

fpminimax(f, n, formats, range, indic1, indic2, indic3, P) : (function, integer, list, range, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, function) → function
fpminimax(f, monomials, formats, range, indic1, indic2, indic3, P) : (function, list, list, range, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, function) → function
fpminimax(f, n, formats, L, indic1, indic2, indic3, P) : (function, integer, list, list, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, function) → function
fpminimax(f, monomials, formats, L, indic1, indic2, indic3, P) : (function, list, list, list, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, absolute|relative | fixed|floating | function, function) → function

Parameters:
• f is the function to be approximated
• n is the degree of the polynomial that must approximate f
• monomials is a list of integers or a list of function. It indicates the basis for the approximation of f
• *formats* is a list indicating the formats that the coefficients of the polynomial must have
• *range* is the interval where the function must be approximated
• *L* is a list of interpolation points used by the method
• *indic1* (optional) is one of the optional indication parameters. See the detailed description below.
• *indic2* (optional) is one of the optional indication parameters. See the detailed description below.
• *indic3* (optional) is one of the optional indication parameters. See the detailed description below.
• *P* (optional) is the minimax polynomial to be considered for solving the problem.

Description:

• *fpminimax* uses a heuristic (but practically efficient) method to find a good polynomial approximation of a function *f* on an interval *range*. It implements the method published in the article:
  Efficient polynomial $L^\infty$-approximations
  Nicolas Brisebarre and Sylvain Chevillard
  Proceedings of the 18th IEEE Symposium on Computer Arithmetic (ARITH 18)
  pp. 169-176

• The basic usage of this command is *fpminimax*(f, *n*, *formats*, *range*). It computes a polynomial approximation of *f* with degree at most *n* on the interval *range*. *formats* is a list of integers or format types (such as *double*, *doubledouble*, etc.). The polynomial returned by the command has its coefficients that fit the formats indications. For instance, if *formats[0]* is 35, the coefficient of degree 0 of the polynomial will fit a floating-point format of 35 bits. If *formats[1]* is D, the coefficient of degree 1 will be representable by a floating-point number with a precision of 53 bits (which is not necessarily an IEEE 754 double precision number. See the remark below), etc.

• The second argument may be either an integer, a list of integers or a list of functions. An integer indicates the degree of the desired polynomial approximation. A list of integers indicates the list of desired monomials. For instance, the list $[0, 2, 4, 6]$ indicates that the polynomial must be even and of degree at most 6. Giving an integer *n* as second argument is equivalent as giving $[0, \ldots, n]$. Finally, a list of function $g_k$ indicates that the desired approximation must be a linear combination of the $g_k$.

  The list of formats is interpreted with respect to the list of monomials. For instance, if the list of monomials is $[0, 2, 4, 6]$ and the list of formats is $[161, 107, 53, 24]$, the coefficients of degree 0 is searched as a floating-point number with precision 161, the coefficient of degree 2 is searched as a number of precision 107, and so on.

• The list of formats may contain either integers or format types (*halfprecision*, *single*, *double*, *doubledouble*, *tripledouble*, *doubleextended* and *quad*). The list may be too large or even infinite. Only the first indications will be considered. For instance, for a degree *n* polynomial, *formats[n + 1]* and above will be discarded. This lets one use elliptical indications for the last coefficients.

• The floating-point coefficients considered by *fpminimax* do not have an exponent range. In particular, in the format list, *double* is an exact synonym for 53. Currently, *fpminimax* only ensures that the corresponding coefficient has at most 53 bits of mantissa. It does not imply that it is an IEEE-754 double.

• By default, the list of formats is interpreted as a list of floating-point formats. This may be changed by passing *fixed* as an optional argument (see below). Let us take an example: *fpminimax*(f, 2, [107, DD, 53], [0;1]). Here the optional argument is missing (we could have set it to *floating*). Thus, *fpminimax* will search for a polynomial of degree 2 with a constant coefficient that is a 107 bits floating-point number, etc.

 Currently, *doubledouble* is just a synonym for 107 and *tripledouble* a synonym for 161. This behavior may change in the future (taking into account the fact that some double-doubles are not
representable with 107 bits).
Second example: \texttt{fpminimax}(f, 2, [25, 18, 30], [0;1], \texttt{fixed}). In this case, \texttt{fpminimax} will search
for a polynomial of degree 2 with a constant coefficient of the form \(m/2^{25}\) where \(m\) is an integer. In
other words, it is a fixed-point number with 25 bits after the point. Note that even with argument
\texttt{fixed}, the formats list is allowed to contain \texttt{halfprecision, single, double, doubleextended, doubledouble, quad} or \texttt{tripledouble}. In this case, it is just a synonym for 11, 24, 53, 64,
107, 113 or 161. This is deprecated and may change in the future.

• The fourth argument may be a range or a list. Lists are for advanced users that know what they
are doing. The core of the method is a kind of approximated interpolation. The list given here is a
list of points that must be considered for the interpolation. It must contain at least as many points
as unknown coefficients. If you give a list, it is also recommended that you provide the minimax
polynomial as last argument. If you give a range, the list of points will be automatically computed.

• The fifth, sixth and seventh arguments are optional. By default, \texttt{fpminimax} will approximate \(f\)
while optimizing the relative error, and interpreting the list of formats as a list of floating-point
formats.
This default behavior may be changed with these optional arguments. You may provide zero,
one, two or three of the arguments in any order. This lets the user indicate only the non-default
arguments.
The three possible arguments are:
– \texttt{relative} or \texttt{absolute}: the error to be optimized;
– \texttt{floating} or \texttt{fixed}: formats of the coefficients;
– a constrained part \(q\).
The constrained part lets the user assign in advance some of the coefficients. For instance, for
approximating \(\exp(x)\), it may be interesting to search for a polynomial \(p\) of the form
\[ p = 1 + x + \frac{x^2}{2} + a_3x^3 + a_4x^4. \]
Thus, there is a constrained part \(q = 1+x+x^2/2\) and the unknown polynomial should be considered
in the monomial basis \([3, 4]\). Calling \texttt{fpminimax} with monomial basis \([3, 4]\) and constrained
part \(q\), will return a polynomial with the right form.

• The last argument is for advanced users. It is the minimax polynomial that approximates the
function \(f\) in the given basis. If it is not given this polynomial will be automatically computed by
\texttt{fpminimax}.
This minimax polynomial is used to compute the list of interpolation points required by the method.
It is also used, when floating-point coefficients are desired, to give an initial assumption for the
exponents of the coefficients. In general, you do not have to provide this argument. But if you want
to obtain several polynomials of the same degree that approximate the same function on the same
range, just changing the formats, you should probably consider computing only once the minimax
polynomial and the list of points instead of letting \texttt{fpminimax} recompute them each time.
Note that in the case when a constrained part is given, the minimax polynomial must take that into
account. For instance, in the previous example, the minimax would be obtained by the following
command:
\[
P = \text{remez}(1-(1+x+x^2/2)/\exp(x), [3,4], \text{range}, 1/\exp(x));
\]
Note that the constrained part is not to be added to \(P\).
In the case when the second argument is an integer or a list of integers, there is no restriction for
\(P\), as long as it is a polynomial. However, when the second argument is a list of functions, and
even if these functions are all polynomials, \(P\) must be expanded in the given basis. For instance,
if the second argument is 2 or \([0, 1, 2]\), \(P\) can be given in Horner form. However, if the second
argument is \([1, x, x^2]\), \(P\) must be written as a linear combination of 1, \(x\) and \(x^2\), otherwise, the
algorithm will fail to recover the coefficients of $P$ and will fail with an error message.

Please also note that recovering the coefficients of $P$ in an arbitrary basis is performed heuristically and no verification is performed to check that $P$ does not contain other functions than the functions of the basis.

- Note that \texttt{fpminimax} internally computes a minimax polynomial (using the same algorithm as \texttt{remez} command). Thus \texttt{fpminimax} may encounter the same problems as \texttt{remez}. In particular, it may be very slow when Haar condition is not fulfilled. Another consequence is that currently \texttt{fpminimax} has to be run with a sufficiently high working precision.

\textbf{Example 1:}

```plaintext
> P = fpminimax(cos(x),6,[|DD, DD, D...|],[-1b-5;1b-5]);
> printexpansion(P);
(0x3ff0000000000000 + 0xbc09fda15e029b00) + x * ((0x3af9eb57163024a8 + 0x37942cf33e3839) + x * (0xbfdffffffff98 + x * (0xbbd1693f9c028849 + x * (0x3fa555555145337 + x * (0x3c7a25f610ad9ebc + x * 0xbf56c138142da5b0))))
```

\textbf{Example 2:}

```
> P = fpminimax(sin(x),6,[|32...|],[-1b-5;1b-5], fixed, absolute);
> display = powers!;
> P;
\text{x * (1 + x^2 * (-357913941 * 2^-31) + x^-2 * (35789873 * 2^-32)))
```

\textbf{Example 3:}

```
> P = fpminimax(exp(x), [3,4], [D,24], [-1/256; 1/246], 1+x+x^2/2);
> display = powers!;
> P;
\text{1 + x * (1 + x * (1 * 2^{-1} + x * (375300225001191 * 2^{-51} + x * (5592621 * 2^{-27}))))}
```

\textbf{Example 4:}

```
> f = cos(exp(x));
> pstar = remez(f, 5, [-1b-7;1b-7]);
> listpoints = dirtyfindzeros(f-pstar, [-1b-7; 1b-7]);
> P1 = fpminimax(f, 5, [|DD...|], listpoints, absolute, default, default, pstar);
> P2 = fpminimax(f, 5, [D...], listpoints, absolute, default, default, pstar);
> P3 = fpminimax(f, 5, [D, D, 24...|], listpoints, absolute, default, default, pstar);
> print("Error of pstar: ", dirtyinfnorm(f-pstar, [-1b-7; 1b-7]));
Error of pstar: 7.90484412599030266580081299123420463921479618202064e-16
> print("Error of P1: ", dirtyinfnorm(f-P1, [-1b-7; 1b-7]));
Error of P1: 7.90484412599030266580081299123420463921479618202064e-16
> print("Error of P2: ", dirtyinfnorm(f-P2, [-1b-7; 1b-7]));
Error of P2: 8.2477144579950871737109573536791331686347620955984e-16
> print("Error of P3: ", dirtyinfnorm(f-P3, [-1b-7; 1b-7]));
Error of P3: 1.084542771569932082593701156841863009789063333951055e-15
```

\textbf{Example 5:}

```plaintext
95
```
> \( L = [\exp(x), \sin(x), \cos(x)-1, \sin(x^3)] \);
> \( g = (2^x-1)/x \);
> \( p = \text{fpminimax}(g, L, [[\text{...}]], [-1/16;1/16], \text{absolute}); \)
> display = powers!;
> p;
-3267884797436153 * 2^{-54} * \sin(x^3) + 5247089102535885 * 2^{-53} * (\cos(x) - 1) + -8159095033730771 * 2^{-54} * \sin(x) + 6243315658446641 * 2^{-53} * \exp(x)

Example 6:

> \( n = 9 \);
> \( T = [1, x] \);
> \text{for i from 2 to n do } T[i] = \text{canonical}(2*x*T[i-1]-T[i-2]);
> \( g = (2^x-1)/x \);
> \( \text{PCheb} = \text{fpminimax}(g, T, [[\text{...}]], [-1/16;1/16], \text{absolute}); \)
> display = dyadic!;
> print(PCheb);
873393009889424731b-98 * (9 * x + -120 * x^3 + 432 * x^5 + -576 * x^7 + 256 * x^9) + 15750497046710770365b-94 * (1 + -32 * x^2 + 160 * x^4 + -256 * x^6 + 128 * x^8) + 646738039858729338b-88 * (-7 * x + 56 * x^3 + -112 * x^5 + 64 * x^7) + 934276260692618927b-84 * (-1 + 18 * x^2 + -48 * x^4 + 32 * x^6) + 1181452136745b-80 * (5 * x + -20 * x^3 + 16 * x^5) + 64054794743285709b-76 * (1 + -8 * x^2 + 8 * x^4) + 115844573247819488b-72 * (-3 * x + 4 * x^3) + 16779705312447201161b-69 * (-1 + 2 * x^2) + 1826501428099735939b-66 * x + 1170544947817514390209975397253b-107

8.70 fullparentheses

Name: fullparentheses
activates, deactivates or inspects the state variable controlling output with full parenthesising

Library names:

void sollya_lib_set_fullparentheses_and_print(sollya_obj_t);
void sollya_lib_set_fullparentheses(sollya_obj_t);
sollya_obj_t sollya_lib_get_fullparentheses();

Usage:

fullparentheses = activation value : on|off → void

fullparentheses = activation value ! : on|off → void

Parameters:

- activation value represents on or off, i.e. activation or deactivation

Description:

An assignment fullparentheses = activation value, where activation value is one of on or off, activates respectively deactivates the output of expressions with full parenthesising. In full parenthesising mode, Sollya commands like print, write and the implicit command when an expression is given at the prompt will output expressions with parenthesising at all places where it is necessary for expressions containing infix operators to be parsed back with the same result. Otherwise parentheses around associative operators are omitted.
If the assignment `fullparentheses = activation value` is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

Example 1:

```
> autosimplify = off;!  
> fullparentheses = off;  
Full parentheses mode has been deactivated.  
> print(1 + 2 + 3);      
1 + 2 + 3                
> fullparentheses = on;  
Full parentheses mode has been activated.  
> print(1 + 2 + 3);      
(1 + 2) + 3
```

See also: `print` (8.132), `write` (8.192), `autosimplify` (8.15)

### 8.71 function

**Name:** function  
keyword for declaring a procedure-based function or a keyword representing a function type

**Library names:**  
sollya_obj_t sollya_lib_procedurefunction(sollya_obj_t, sollya_obj_t)  
sollya_obj_t sollya_lib_build_function_procedurefunction(sollya_obj_t, sollya_obj_t)

**Usage:**

function(procedure) : procedure → function  
function : type type

**Parameters:**

- `procedure` is a procedure of type `(range, integer, integer) → range`

**Description:**

- For the sake of safety and mathematical consistency, Sollya distinguishes clearly between functions, seen in the mathematical sense of the term, i.e. mappings, and procedures, seen in the sense Computer Science gives to functions, i.e. pieces of code that compute results for arguments following an algorithm. In some cases however, it is interesting to use such Computer Science procedures as realisations of mathematical functions, e.g. in order to plot them or even to perform polynomial approximation on them. The function keyword allows for such a transformation of a Sollya procedure into a Sollya function.

- The procedure to be used as a function through `function(procedure)` must be of type `(range, integer, integer) → range`. This means it must take in argument an interval `X`, a degree of differentiation `n` and a working precision `p`. It must return in result an interval `Y` encompassing the image `f^{(n)}(X)` of the `n`-th derivative of the implemented function `f`, i.e. `f^{(n)}(X) ⊆ Y`. In order to allow Sollya’s algorithms to work properly, the procedure must ensure that, whenever `(p, diam(X))` tends to `(+-∞, 0)`, the computed over-estimated bounding `Y` tends to the actual image `f^{(n)}(X)`.

- The user must be aware that they are responsible of the correctness of the procedure. If, for some `n` and `X`, `procedure` returns an interval `Y` such that `f^{(n)}(X) ⊈ Y`, `function` will successfully return a function without any complain, but this function might behave inconsistently in further computations.

- For cases when the procedure does not have the correct signature or does not return a finite interval as a result `function(procedure)` evaluates to Not-A-Number (resp. to an interval of Not-A-Numbers for interval evaluation).
• **function** also represents the function type for declarations of external procedures by means of `externalproc`.

Remark that in contrast to other indicators, type indicators like **function** cannot be handled outside the `externalproc` context. In particular, they cannot be assigned to variables.

Example 1:
> procedure EXP(X,n,p) {
    var res, oldPrec;
    oldPrec = prec;
    prec = p!;
    res = exp(X);
    prec = oldPrec!;
    return res;
};
> f = function(EXP);
> f(1);

\]

Usage:

\[
\text{expr1} \geq \text{expr2} : (\text{constant, constant}) \to \text{boolean}
\]

Parameters:

- \( \text{expr1} \) and \( \text{expr2} \) represent constant expressions

Description:

- The operator \( \geq \) evaluates to true if its operands \( \text{expr1} \) and \( \text{expr2} \) evaluate to two floating-point numbers \( a_1 \) respectively \( a_2 \) with the global precision \( \text{prec} \) and \( a_1 \) is greater than or equal to \( a_2 \).

Example 1:

\[
\begin{align*}
> \ 5 \ \geq \ 4; \\
& \quad \text{true} \\
> \ 5 \ \geq \ 5; \\
& \quad \text{true} \\
> \ 5 \ \geq \ 6; \\
& \quad \text{false} \\
> \ \text{exp}(2) \ \geq \ \text{exp}(1); \\
& \quad \text{true} \\
> \ \text{log}(1) \ \geq \ \text{exp}(2); \\
& \quad \text{false}
\end{align*}
\]

Example 2:

\[
\begin{align*}
> \ \text{prec} = 12; \\
& \quad \text{The precision has been set to 12 bits.} \\
> \ 16384.1 \ \geq \ 16385.1; \\
& \quad \text{true}
\end{align*}
\]

See also: \( \leq \) (8.51), \( != \) (8.101), \( > \) (8.74), \( <= \) (8.92), \( < \) (8.101), \( \text{in} \) (8.85), \( ! \) (8.112), \&\& (8.6), || (8.118), prec (8.129), max (8.103), min (8.106)

8.73 getsuppressedmessages

Name: getsuppressedmessages

returns a list of numbers of messages that have been suppressed from message output

Library name:

\[
\text{sollya} \_\text{obj} \_\text{t} \ \text{sollya} \_\text{lib} \_\text{getsuppressedmessages}();
\]

Usage:

\[
\text{getsuppressedmessages}() : \text{void} \to \text{list}
\]

Description:
• The **getsuppressedmessages** command allows the user to inspect the state of warning and information message suppression. When called, **getsuppressedmessages** returns a list of integers numbers that stand for the warning and information messages that have been suppressed. If no message is suppressed, **getsuppressedmessages** returns an empty list.

• Every Sollya warning or information message (that is not fatal to the tool’s execution) has a message number. By default, these numbers are not displayed when a message is output. When message number displaying is activated using **showmessagenumbers**, the message numbers are displayed together with the message. This allows the user to match the numbers returned in a list by **getsuppressedmessages** with the actual warning and information messages.

• The list of message numbers returned by **getsuppressedmessages** is suitable to be fed into the **unsuppressmessage** command. This way, the user may unsuppress all warning and information messages that have been suppressed.

**Example 1:**

```
> verbosity = 1;
The verbosity level has been set to 1.
> 0.1;
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
0.1
> suppressmessage(174);
> 0.1;
0.1
> suppressmessage(407);
> 0.1;
0.1
> getsuppressedmessages();
[174, 407]
> suppressmessage(207, 196);
> unsuppressmessage(174, 196);
> unsuppressmessage([13, 17]);
[174, 196, 207, 407]
```

**Example 2:**

```
> suppressmessage(174, 209, 13, 24, 196);
> suppressmessage([16, 17]);
> suppressmessage(19);
> unsuppressmessage([13, 17]);
> getsuppressedmessages();
[16, 19, 24, 174, 196, 209]
> unsuppressmessage(getsuppressedmessages());
> getsuppressedmessages();
[]
```

**Example 3:**
> verbosity = 12;
The verbosity level has been set to 12.
> suppressmessage(174);
> exp(x * 0.1);
Information: no Horner simplification will be performed because the given tree i
s already in Horner form.
exp(x * 0.1)
> getsuppressedmessages();
[174]
> verbosity = 0;
The verbosity level has been set to 0.
> exp(x * 0.1);
> getsuppressedmessages();
[174]
See also: getsuppressedmessages [8.73], suppressmessage [8.175], unsuppressmessage [8.187],
verbosity [8.189], roundingwarnings [8.158]

8.74  >
Name: >

greater-than operator
Library name:
  sollya_obj_t sollya_lib_cmp_greater(sollya_obj_t, sollya_obj_t)
Usage:

  expr1 > expr2 : (constant, constant) → boolean

Parameters:
  • expr1 and expr2 represent constant expressions
Description:
  • The operator > evaluates to true iff its operands expr1 and expr2 evaluate to two floating-point
    numbers $a_1$ respectively $a_2$ with the global precision prec and $a_1$ is greater than $a_2$. The user
    should be aware of the fact that because of floating-point evaluation, the operator > is not exactly
    the same as the mathematical operation greater-than.

Example 1:

> 5 > 4;
true
> 5 > 5;
false
> 5 > 6;
false
> exp(2) > exp(1);
true
> log(1) > exp(2);
false

Example 2:

> prec = 12;
The precision has been set to 12 bits.
> 16385.1 > 16384.1;
false
8.75  **guessdegree**

Name: **guessdegree**  
returns the minimal degree needed for a polynomial to approximate a function with a certain error on an interval.

Library names:

sollya_obj_t sollya_lib_guessdegree(sollya_obj_t, sollya_obj_t, sollya_obj_t, ...)  
sollya_obj_t sollya_lib_v_guessdegree(sollya_obj_t, sollya_obj_t, sollya_obj_t, va_list)

Usage:

\[
\text{guessdegree}(f, I, \text{eps}, w, \text{bound}) : (\text{function}, \text{range}, \text{constant}, \text{function}, \text{constant}) \rightarrow \text{range}
\]

Parameters:

- \(f\) is the function to be approximated.
- \(I\) is the interval where the function must be approximated.
- \(\text{eps}\) is the maximal acceptable error.
- \(w\) (optional) is a weight function. Default is 1.
- \(\text{bound}\) (optional) is a bound on the degree. Default is currently 128.

Description:

- **guessdegree** tries to find the minimal degree needed to approximate \(f\) on \(I\) by a polynomial with an error \(\epsilon = pw - f\) whose infinity norm not greater than \(\text{eps}\). More precisely, it finds \(n\) minimal such that there exists a polynomial \(p\) of degree \(n\) such that \(\|pw - f\|_\infty < \text{eps}\).
- **guessdegree** returns an interval: for common cases, this interval is reduced to a single number (i.e. the minimal degree). But in certain cases, **guessdegree** does not succeed in finding the minimal degree. In such cases the returned interval is of the form \([n, p]\) such that:
  - no polynomial of degree \(n\) gives an error less than \(\text{eps}\).
  - there exists a polynomial of degree \(p\) giving an error less than \(\text{eps}\).
- The fifth optional argument \(\text{bound}\) is used to prevent **guessdegree** from trying to find too large degrees. If **guessdegree** does not manage to find a degree \(n\) satisfying the error and such that \(n \leq \text{bound}\), an interval of the form \([-\infty, +\infty]\) is returned. Note that \(\text{bound}\) must be a positive integer.

Example 1:

\[
> \text{guessdegree}(\exp(x), [-1;1], 1e-10);
[10;10]
\]

Example 2:

\[
> \text{guessdegree}(\exp(x), [-1;1], 1e-10, \text{default}, 9);
[10;@\text{Inf}@]
\]

Example 3:

\[
> \text{guessdegree}(1, [-1;1], 1e-8, 1/\exp(x));
[8;9]
\]

See also: **dirtyinfnorm** (8.42), **remez** (8.149), **fpminimax** (8.69), **degree** (8.36)
8.76 halfprecision

Names: halfprecision, HP
rounding to the nearest IEEE 754 half-precision number (binary16).

Library names:
- sollya_obj_t sollya_lib_halfprecision(sollya_obj_t)
- sollya_obj_t sollya_lib_halfprecision_obj()
- int sollya_lib_is_halfprecision_obj(sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_halfprecision(sollya_obj_t)
- #define SOLLYA_HP(x) sollya_lib_build_function_halfprecision(x)

Description:
- **halfprecision** is both a function and a constant.
- As a function, it rounds its argument to the nearest IEEE 754 half-precision (i.e. IEEE754-2008 binary16) number. Subnormal numbers are supported as well as standard numbers: it is the real rounding described in the standard.
- As a constant, it symbolizes the half-precision format. It is used in contexts when a precision format is necessary, e.g. in the commands round and roundcoefficients. It is not supported for implementpoly. See the corresponding help pages for examples.

Example 1:

```plaintext
> display=binary!;
> HP(0.1);
1.100110011_2 * 2^(-4)
> HP(4.17);
1.00001011_2 * 2^(2)
> HP(1.011_2 * 2^(-23));
1.1_2 * 2^(-23)
```

See also: single [8.166], double [8.47], doubleextended [8.49], doubledouble [8.48], quad [8.140], tripledouble [8.185], roundcoefficients [8.156], fpminimax [8.69], implementpoly [8.84], round [8.155], printsingle [8.135]

8.77 head

Name: head
gives the first element of a list.

Library name:
- sollya_obj_t sollya_lib_head(sollya_obj_t)

Usage:

```
head(L) : list → any type
```

Parameters:
- **L** is a list.

Description:
- **head(L)** returns the first element of the list L. It is equivalent to L[0].
- If L is empty, the command will fail with an error.

Example 1:

```plaintext
> head([1, 2, 3, 4]);
1
```

See also: list [8.09], listify [8.09], concat [8.11], project [8.14], slice [8.14], flatten [8.15], unfold [8.17], fold [8.17], map [8.17], zip [8.17], length [8.35]
8.78 hexadecimal

Name: hexadecimal

special value for global state display

Library names:

sollya_obj_t sollya_lib_hexadecimal()

int sollya_lib_is_hexadecimal(sollya_obj_t)

Description:

- **hexadecimal** is a special value used for the global state display. If the global state display is equal to hexadecimal, all data will be output in hexadecimal C99/IEEE 754-2008 notation.

As any value it can be affected to a variable and stored in lists.

See also: decimal (8.34), dyadic (8.50), powers (8.128), binary (8.18), display (8.45)

8.79 honorcoeffprec

Name: honorcoeffprec

indicates the (forced) honoring the precision of the coefficients in implementpoly

Library names:

sollya_obj_t sollya_lib_honorcoeffprec()

int sollya_lib_is_honorcoeffprec(sollya_obj_t)

Usage:

honorcoeffprec : honorcoeffprec

Description:

- Used with command implementpoly, honorcoeffprec makes implementpoly honor the precision of the given polynomial. This means if a coefficient needs a double-double or a triple-double to be exactly stored, implementpoly will allocate appropriate space and use a double-double or triple-double operation even if the automatic (heuristic) determination implemented in command implementpoly indicates that the coefficient could be stored on less precision or, respectively, the operation could be performed with less precision. See implementpoly for details.

Example 1:
verbosity = 1;
q = implementpoly(1 - dirtysimplify(TD(1/6)) * x^2, [-1b-10;1b-10],1b-60,DD,"p","implementation.c");
Warning: at least one of the coefficients of the given polynomial has been rounded in a way that the target precision can be achieved at lower cost. Nevertheless, the implemented polynomial is different from the given one.
printexpansion(q);
0x3ff0000000000000 + x^2 * 0xbfc5555555555555
r = implementpoly(1 - dirtysimplify(TD(1/6)) * x^2, [-1b-10;1b-10],1b-60,DD,"p","implementation.c",honorcoeffprec);
Warning: the inferred precision of the 2th coefficient of the polynomial is greater than the necessary precision computed for this step. This may make the automatic determination of precisions useless.
printexpansion(r);
0x3ff0000000000000 + x^2 * (0xbfc5555555555555 + 0xbc65555555555555 + 0xb905555555555555)

See also: implementpoly (8.84), printexpansion (8.134), fpminimax (8.69)

8.80 hopitalrecursions
Name: hopitalrecursions
controls the number of recursion steps when applying L'Hopital's rule.

Library names:
void sollya_lib_set_hopitalrecursions_and_print(sollya_obj_t)
void sollya_lib_set_hopitalrecursions(sollya_obj_t)
sollya_obj_t sollya_lib_get_hopitalrecursions()

Usage:

hopitalrecursions = n : integer → void
hopitalrecursions = n ! : integer → void
hopitalrecursions : integer

Parameters:
• n represents the number of recursions

Description:
• hopitalrecursions is a global variable. Its value represents the number of steps of recursion that are tried when applying L'Hopital's rule. This rule is applied by the interval evaluator present in the core of Sollya (and particularly visible in commands like infnorm).
• If an expression of the form f/g has to be evaluated by interval arithmetic on an interval I and if f and g have a common zero in I, a direct evaluation leads to NaN. Sollya implements a safe heuristic to avoid this, based on L'Hopital's rule: in such a case, it can be shown that (f/g)(I) ⊆ (f'/g')(I). Since the same problem may exist for f'/g', the rule is applied recursively. The number of step in this recursion process is controlled by hopitalrecursions.
• Setting hopitalrecursions to 0 makes Sollya use this rule only once; setting it to 1 makes Sollya use the rule twice, and so on. In particular: the rule is always applied at least once, if necessary.

Example 1:
> hopitalrecursions=0;
The number of recursions for Hopital’s rule has been set to 0.
> evaluate(log(1+x)^2/x^2,[-1/2; 1]);
[-@Inf@;@Inf@]
> hopitalrecursions=1;
The number of recursions for Hopital’s rule has been set to 1.
> evaluate(log(1+x)^2/x^2,[-1/2; 1]);
[-2.5225887223978123766892848583270627230200053744108;6.7725887223978123766892
84858327062723020005374411]

See also: taylorrecursions (8.181), infnorm (8.87), findzeros (8.65), evaluate (8.55)

8.81 horner

Name: horner

brings all polynomial subexpressions of an expression to Horner form

Library name:

sollya_obj_t sollya_lib_horner(sollya_obj_t)

Usage:

horner(function) : function → function

Parameters:

• function represents the expression to be rewritten in Horner form

Description:

• The command horner rewrites the expression representing the function function in a way such that all polynomial subexpressions (or the whole expression itself, if it is a polynomial) are written in Horner form. The command horner does not endanger the safety of computations even in Sollya’s floating-point environment: the function returned is mathematically equal to the function function.

Example 1:

> print(horner(1 + 2 * x + 3 * x^-2));
1 + x * (2 + x * 3)
> print(horner((x + 1)^7));
1 + x * (7 + x * (21 + x * (35 + x * (35 + x * (21 + x * (7 + x))))))

Example 2:

> print(horner(exp((x + 1)^5) - log(asin(x + x^3) + x));
exp(1 + x * (5 + x * (10 + x * (10 + x * (5 + x))))) - log(asin(x * (1 + x^-2)) + x

See also: canonical (8.21), print (8.132), coeff (8.25), degree (8.36), autosimplify (8.15), simplify (8.164)

8.82 HP

Name: HP

short form for halfprecision

See also: halfprecision (8.76)
8.83 implementconstant

Name: implementconstant
    implements a constant in arbitrary precision

Library names:
    void sollya_lib_implementconstant(sollya_obj_t, ...);
    void sollya_lib_v_implementconstant(sollya_obj_t, va_list);

Usage:

    implementconstant(expr) : constant → void
    implementconstant(expr, filename) : (constant, string) → void
    implementconstant(expr, filename, functionname) : (constant, string, string) → void

Description:

• The command implementconstant implements the constant expression expr in arbitrary precision. More precisely, it generates the source code (written in C, and using MPFR) of a C function const_something with the following signature:

      void const_something (mpfr_ptr y, mp_prec_t prec)

    Let us denote by $c$ the exact mathematical value of the constant defined by the expression expr. When called with arguments $y$ and prec (where the variable $y$ is supposed to be already initialized), the function mpfr_const_something sets the precision of $y$ to a suitable precision and stores in it an approximate value of $c$ such that

    \[ |y - c| \leq |c| 2^{1-\text{prec}}. \]

• When no filename filename is given or if default is given as filename, the source code produced by implementconstant is printed on standard output. Otherwise, when filename is given as a string of characters, the source code is output to a file named filename. If that file cannot be opened and/or written to, implementconstant fails and has no other effect.

• When functionname is given as an argument to implementconstant and functionname evaluates to a string of characters, the default name for the C function const_something is replaced by functionname. When default is given as functionname, the default name is used nevertheless, as if no functionname argument were given. When choosing a character sequence for functionname, the user should keep attention to the fact that functionname must be a valid C identifier in order to enable error-free compilation of the produced code.

• If expr refers to a constant defined with libraryconstant, the produced code uses the external code implementing this constant. The user should keep in mind that it is up to them to make sure the symbol for that external code can get resolved when the newly generated code is to be loaded.

• If a subexpression of expr evaluates to 0, implementconstant will most likely fail with an error message.

• implementconstant is unable to implement constant expressions expr that contain procedure-based functions, i.e. functions created from Sollya procedures using the function construct. If expr contains such a procedure-based function, implementconstant prints a warning and fails silently. The reason for this lack of functionality is that the produced C source code, which is supposed to be compiled, would have to call back to the Sollya interpreter in order to evaluate the procedure-based function.

• Similarly, implementconstant is currently unable to implement constant expressions expr that contain library-based functions, i.e. functions dynamically bound to Sollya using the library construct. If expr contains such a library-based function, implementconstant prints a warning and fails silently. Support for this feature is in principle feasible from a technical standpoint and might be added in a future release of Sollya.
• Currently, non-differentiable functions such as double, doubledouble, tripledouble, single, halfprecision, quad, doubleextended, floor, ceil, nearestint are not supported by implementconstant. If implementconstant encounters one of them, a warning message is displayed and no code is produced. However, if autosimplify equals on, it is possible that Sollya silently simplifies subexpressions of expr containing such functions and that implementconstant successfully produces code for evaluating expr.

• While it produces an MPFR-based C source code for expr, implementconstant takes architectural and system-dependent parameters into account. For example, it checks whether literal constants figuring in expr can be represented on a C long int type or if they must be stored in a different manner not to affect their accuracy. These tests, performed by Sollya during execution of implementconstant, depend themselves on the architecture Sollya is running on. Users should keep this matter in mind, especially when trying to compile source code on one machine whilst it has been produced on another.

Example 1:
implementconstant(exp(1)+log(2)/sqrt(1/10));
/*

The Sollya software is a computer program whose purpose is to provide
an environment for safe floating-point code development. It is
particularly targeted to the automatized implementation of
mathematical floating-point libraries (libm). Amongst other features,
it offers a certified infinity norm, an automatic polynomial
implementer and a fast Remez algorithm.

The Sollya software is governed by the CeCILL-C license under French
law and abiding by the rules of distribution of free software. You
can use, modify and/ or redistribute the software under the terms of
the CeCILL-C license as circulated by CEA, CNRS and INRIA at the
following URL "http://www.cecill.info".

As a counterpart to the access to the source code and rights to copy,
modify and redistribute granted by the license, users are provided
only with a limited warranty and the software’s author, the holder
of the economic rights, and the successive licensors have only limited
liability.

In this respect, the user’s attention is drawn to the risks associated
with loading, using, modifying and/ or developing or reproducing
the software by the user in light of its specific status of free software,
that may mean that it is complicated to manipulate, and that also
therefore means that it is reserved for developers and experienced
professionals having in-depth computer knowledge. Users are therefore
couraged to load and test the software’s suitability as regards
their requirements in conditions enabling the security of their
systems and/ or data to be ensured and, more generally, to use and
operate it in the same conditions as regards security.

The fact that you are presently reading this means that you have had
knowledge of the CeCILL-C license and that you accept its terms.

The Sollya software is a computer program whose purpose is to provide
an environment for safe floating-point code development. It is
particularly targeted to the automatized implementation of
mathematical floating-point libraries (libm). Amongst other features,
it offers a certified infinity norm, an automatic polynomial
implementer and a fast Remez algorithm.

The Sollya software is governed by the CeCILL-C license under French
law and abiding by the rules of distribution of free software. You
can use, modify and/or redistribute the software under the terms of
the CeCILL-C license as circulated by CEA, CNRS and INRIA at the
following URL "http://www.cecill.info".

As a counterpart to the access to the source code and rights to copy,
modify and redistribute granted by the license, users are provided
only with a limited warranty and the software’s author, the holder of
the economic rights, and the successive licensors have only limited
liability.

In this respect, the user’s attention is drawn to the risks associated
with loading, using, modifying and/or developing or reproducing the
software by the user in light of its specific status of free software,
that may mean that it is complicated to manipulate, and that also
therefore means that it is reserved for developers and experienced
professionals having in-depth computer knowledge. Users are therefore
encouraged to load and test the software’s suitability as regards
their requirements in conditions enabling the security of their
systems and/or data to be ensured and, more generally, to use and
operate it in the same conditions as regards security.

The fact that you are presently reading this means that you have had
knowledge of the CeCILL-C license and that you accept its terms.

8.84 implementpoly

Name: implementpoly

implements a polynomial using double, double-double and triple-double arithmetic and generates a Gappa proof

Library names:

sollya_obj_t sollya_lib_implementpoly(sollya_obj_t, sollya_obj_t, sollya_obj_t, sollya_obj_t, ...)  
sollya_obj_t sollya_lib_v_implementpoly(sollya_obj_t, sollya_obj_t, sollya_obj_t, sollya_obj_t, ...)  

Usage:

implementpoly(polynomial, range, error bound, format, functionname, filename) : (function, range, constant, D|double|DD|doubledouble|TD|tripledouble, string, string) \rightarrow function

implementpoly(polynomial, range, error bound, format, functionname, filename, honor coefficient precisions) : (function, range, constant, D|double|DD|doubledouble|TD|tripledouble, string, string, honorcoeffprec) \rightarrow function

implementpoly(polynomial, range, error bound, format, functionname, filename, proof filename) : (function, range, constant, D|double|DD|doubledouble|TD|tripledouble, string, string, proof filename) \rightarrow function

implementpoly(polynomial, range, error bound, format, functionname, filename, honor coefficient precisions, proof filename) : (function, range, constant, D|double|DD|doubledouble|TD|tripledouble, string, string, honorcoeffprec, string) \rightarrow function

Description:

- The command implementpoly implements the polynomial polynomial in range range as a function called functionname in C code using double, double-double and triple-double arithmetic in a way that the rounding error (estimated at its first order) is bounded by error bound. The produced code is output in a file named filename. The argument format indicates the double, double-double or triple-double format of the variable in which the polynomial varies, influencing also in the signature of the C function.

If a seventh or eighth argument proof filename is given and if this argument evaluates to a variable of type string, the command implementpoly will produce a Gappa proof that the rounding error is less than the given bound. This proof will be output in Gappa syntax in a file name proof filename. The command implementpoly returns the polynomial that has been implemented. As the command implementpoly tries to adapt the precision needed in each evaluation step to its strict minimum and as it applies renormalization to double-double and triple-double precision coefficients to bring them to a round-to-nearest expansion form, the returned polynomial may differ from the polynomial polynomial. Nevertheless the difference will be small enough that the rounding error bound with regard to the polynomial polynomial (estimated at its first order) will be less than the given error bound.

If a seventh argument honor coefficient precisions is given and evaluates to a variable honorcoeffprec of type honorcoeffprec, implementpoly will honor the precision of the given polynomial polynomials. This means if a coefficient needs a double-double or a triple-double to be exactly stored, implementpoly will allocate appropriate space and use a double-double or triple-double operation even if the automatic (heuristic) determination implemented in command implementpoly indicates that the coefficient could be stored on less precision or, respectively, the operation could be performed with less precision. The use of honorcoeffprec has advantages and disadvantages. If the polynomial polynomial given has not been determined by a process considering directly polynomials with floating-point coefficients, honorcoeffprec should not be indicated. The implementpoly command can then determine the needed precision using the same error estimation as used for the determination of the precisions of the operations. Generally, the coefficients...
will get rounded to double, double-double and triple-double precision in a way that minimizes their number and respects the rounding error bound *error bound*. Indicating *honorcoeffprec* may in this case short-circuit most precision estimations leading to sub-optimal code. On the other hand, if the polynomial *polynomial* has been determined with floating-point precisions in mind, *honorcoeffprec* should be indicated because such polynomials often are very sensitive in terms of error propagation with regard to their coefficients’ values. Indicating *honorcoeffprec* prevents the implementpoly command from rounding the coefficients and altering by many orders of magnitude the approximation error of the polynomial with regard to the function it approximates.

The implementer behind the implementpoly command makes some assumptions on its input and verifies them. If some assumption cannot be verified, the implementation will not succeed and implementpoly will evaluate to a variable *error* of type error. The same behaviour is observed if some file is not writable or some other side-effect fails, e.g. if the implementer runs out of memory.

As error estimation is performed only on the first order, the code produced by the implementpoly command should be considered valid iff a Gappa proof has been produced and successfully run in Gappa.

The Sollya software is a computer program whose purpose is to provide an environment for safe floating-point code development. It is particularly targeted to the automatized implementation of mathematical floating-point libraries (libm). Amongst other features, it offers a certified infinity norm, an automatic polynomial implemener and a fast Remez algorithm.

The Sollya software is governed by the CeCILL-C license under French law and abiding by the rules of distribution of free software. You can use, modify and/ or redistribute the software under the terms of the CeCILL-C license as circulated by CEA, CNRS and INRIA at the following URL "http://www.cecill.info".

As a counterpart to the access to the source code and rights to copy, modify and redistribute granted by the license, users are provided only with a limited warranty and the software’s author, the holder of the economic rights, and the successive licensors have only limited liability.

In this respect, the user’s attention is drawn to the risks associated with loading, using, modifying and/or developing or reproducing the software by the user in light of its specific status of free software, that may mean that it is complicated to manipulate, and that also therefore means that it is reserved for developers and experienced professionals having in-depth computer knowledge. Users are therefore encouraged to load and test the software’s suitability as regards their requirements in conditions enabling the security of their systems and/or data to be ensured and, more generally, to use and operate it in the same conditions as regards security.
Example 2:

```plaintext
> implementpoly(1 - 1/6 * x^2 + 1/120 * x^4, [-1b-10;1b-10], 1b-30, D, "p","implementation.gappa");
1 + x^2 * (-0.166666666666666657414808128123695496469736099243164 + x^2 * 8.333333333332176851016015461937058717012405395e-3)
```

Example 3:

```plaintext
> verbosity = 1!
> q = implementpoly(1 - dirtysimplify(TD(1/6)) * x^2,[-1b-10;1b-10],1b-60,DD,"p","implementation.c"");
Warning: at least one of the coefficients of the given polynomial has been rounded in a way that the target precision can be achieved at lower cost. Nevertheless, the implemented polynomial is different from the given one.
> printexpansion(q);
0x3ff0000000000000 + x^2 * 0xbfc5555555555555
> r = implementpoly(1 - dirtysimplify(TD(1/6)) * x^2,[-1b-10;1b-10],1b-60,DD,"p","implementation.c",honorcoeffprec);
Warning: the inferred precision of the 2th coefficient of the polynomial is greater than the necessary precision computed for this step. This may make the automatic determination of precisions useless.
> printexpansion(r);
0x3ff0000000000000 + x^2 * (0xbfc5555555555555 + 0xbc65555555555555 + 0xb905555555555555)
```

Example 4:

```plaintext
> p = 0x3ff0000000000000 + x * (0x3ff0000000000000 + x * (0x3fe0000000000000 + x * (0x3fc5555555555559 + x * (0x3fa55555555555bd + x * (0x3f811111111106e2 + x * (0x3f56c16c16bf5eb7 + x * (0x3f2a01a0a292dcd + x * (0x3efa01a0218a016a + x * (0x3e71de360331aad + x * (0x3e927e42e3823bf3 + x * (0x3e5ae6b2710c2c9a + x * (0x3e2203730a7c1d + x * 0x3de5da557e0781df))))))))))))));
> q = implementpoly(p,[-1/2;1/2],1b-60,D,"p","implementation.c",honorcoeffprec,"implementation.gappa");
> if (q != p) then print("During implementation, rounding has happened.") else print("Polynomial implemented as given.");
Polynomial implemented as given.
```

### 8.85 in

**Name:** in

- containment test operator

**Library name:**

```plaintext
sollya_obj_t sollya_lib_cmp_in(sollya_obj_t, sollya_obj_t, sollya_obj_t)
```

**Usage:**

```plaintext
expr in range1 : (constant, range) → boolean
range1 in range2 : (range, range) → boolean
```
Parameters:

- `expr` represents a constant expression
- `range1` and `range2` represent ranges (intervals)

Description:

- When its first operand is a constant expression `expr`, the operator `in` evaluates to true iff the constant value of the expression `expr` is contained in the interval `range1`.
- When both its operands are ranges (intervals), the operator `in` evaluates to true iff all values in `range1` are contained in the interval `range2`.
- `in` is also used as a keyword for loops over the different elements of a list.

Example 1:

```plaintext
> 5 in [-4;7];
true
> 4 in [-1;1];
false
> 0 in sin([-17;17]);
true
```

Example 2:

```plaintext
> [5;7] in [2;8];
true
> [2;3] in [4;5];
false
> [2;3] in [2.5;5];
false
```

Example 3:

```plaintext
> for i in [1,...,5] do print(i);
1
2
3
4
5
```

See also: `==` (8.51), `!=` (8.110), `>=` (8.72), `>` (8.74), `<=` (8.92), `<` (8.101), `!` (8.112), `&&` (8.6), `||` (8.118), `prec` (8.129), `print` (8.132)

### 8.86 inf

**Name:** inf

- gives the lower bound of an interval.

**Library name:**

```
sollya_obj_t sollya_lib_inf(sollya_obj_t)
```

**Usage:**

```
inf(l) : range → constant
inf(x) : constant → constant
```

**Parameters:**
• $I$ is an interval.
• $x$ is a real number.

Description:
• Returns the lower bound of the interval $I$. Each bound of an interval has its own precision, so this command is exact, even if the current precision is too small to represent the bound.
• When called on a real number $x$, $\text{inf}$ behaves like the identity.

Example 1:

```
> inf([1;3]);
1
> inf(0);
0
```

Example 2:

```
> display=binary!;
> I=[0.111110000011111_2; 1];
> inf(I);
1.11110000011111_2 * 2^(-1)
> prec=12!;
> inf(I);
1.11110000011111_2 * 2^(-1)
```

See also: $\text{mid}$ [8.104], $\text{sup}$ [8.173], $\text{max}$ [8.103], $\text{min}$ [8.106]

8.87 infnorm

Name: infnorm

computes an interval bounding the infinity norm of a function on an interval.

Library names:

```
sollya_obj_t sollya_lib_infnorm(sollya_obj_t, sollya_obj_t, ...)
sollya_obj_t sollya_lib_v_infnorm(sollya_obj_t, sollya_obj_t, va_list)
```

Usage:

```
infnorm(f,I,filename,Ilist) : (function, range, string, list) → range
```

Parameters:

• $f$ is a function.
• $I$ is an interval.
• $filename$ (optional) is the name of the file into a proof will be saved.
• $IList$ (optional) is a list of intervals to be excluded.

Description:

• $\text{infnorm}(f, range)$ computes an interval bounding the infinity norm of the given function $f$ on the interval $I$, e.g. computes an interval $J$ such that $\max_{x \in I} \{ |f(x)| \} \subseteq J$.
• If $filename$ is given, a proof in English will be produced (and stored in file called $filename$) proving that $\max_{x \in I} \{ |f(x)| \} \subseteq J$.
• If a list $IList$ of intervals $I_1, \ldots, I_n$ is given, the infinity norm will be computed on $I \setminus (I_1 \cup \ldots \cup I_n)$. 

124
The function $f$ is assumed to be at least twice continuous on $I$. More generally, if $f$ is $C^k$, global variables `hopitalrecursions` and `taylorrecursions` must have values not greater than $k$.

If the interval is reduced to a single point, the result of `infnorm` is an interval containing the exact absolute value of $f$ at this point.

If the interval is not bound, the result will be $[0, +\infty]$ which is correct but perfectly useless. `infnorm` is not meant to be used with infinite intervals.

The result of this command depends on the global variables `prec`, `diam`, `taylorrecursions` and `hopitalrecursions`. The contribution of each variable is not easy even to analyse.

- The algorithm uses interval arithmetic with precision `prec`. The precision should thus be set high enough to ensure that no critical cancellation will occur.
- When an evaluation is performed on an interval $[a, b]$, if the result is considered being too large, the interval is split into $[a, \frac{a+b}{2}]$ and $[\frac{a+b}{2}, b]$ and so on recursively. This recursion step is not performed if the $(b-a) < \delta \cdot |I|$ where $\delta$ is the value of variable `diam`. In other words, `diam` controls the minimum length of an interval during the algorithm.
- To perform the evaluation of a function on an interval, Taylor’s rule is applied, e.g. $f([a, b]) \subseteq f(m) + [a-m, b-m] \cdot f’([a, b])$ where $m = \frac{a+b}{2}$. This rule is recursively applied $n$ times where $n$ is the value of variable `taylorrecursions`. Roughly speaking, the evaluations will avoid decorrelation up to order $n$.
- When a function of the form $\frac{g}{h}$ has to be evaluated on an interval $[a, b]$ and when $g$ and $h$ vanish at a same point $z$ of the interval, the ratio may be defined even if the expression $\frac{g(z)}{h(z)} = 0$ does not make any sense. In this case, L’Hopital’s rule may be used and $\frac{(g,h)}{[a, b]} \subseteq \left( \frac{g’}{h’} \right) ([a, b])$.
  Since the same can occur with the ratio $\frac{g’}{h’}$, the rule is applied recursively. The variable `hopitalrecursions` controls the number of recursion steps.

The algorithm used for this command is quite complex to be explained here. Please find a complete description in the following article:

S. Chevillard and C. Lauter
A certified infinity norm for the implementation of elementary functions
LIP Research Report number RR2007-26
http://prunel.ccsd.cnrs.fr/ensl-00119810

Users should be aware about the fact that the algorithm behind `infnorm` is inefficient in most cases and that other, better suited algorithms, such as `supnorm`, are available inside Sollya. As a matter of fact, while `infnorm` is maintained for compatibility reasons with legacy Sollya codes, users are advised to avoid using `infnorm` in new Sollya scripts and to replace it, where possible, by the `supnorm` command.

Example 1:

```plaintext
> infnorm(exp(x),[-2;3]);
[2.00855369218766774928529654581717896987907838553e1;2.008553692187667749285296545817178969879078385544e1]
```

Example 2:

```plaintext
> infnorm(exp(x),[-2;3],"proof.txt");
[2.00855369218766774928529654581717896987907838553e1;2.008553692187667749285296545817178969879078385544e1]
```

Example 3:
Example 4:

> infnorm(exp(x), [-2;3], "proof.txt", [ [0;1], [2;2.5] ]);  
[2.008553692318766777409285296545817178969879078385537e1;2.008553692318766777409285296545817178969879078385544e1]

Example 5:

> infnorm(exp(x), [1;1]);  
[2.71828182845904523536028747135266249775724709369989;2.71828182845904523536028747135266249775724709369998]

Example 6:

> infnorm(exp(x), [log(0);log(1)]);  
[0;@Inf@]

See also: prec (8.129), diam (8.38), hopitalrecursions (8.80), taylorrecursions (8.181), dirty-infnorm (8.182), checkinfnorm (8.24), supnorm (8.174), findzeros (8.65), diff (8.40), taylorrecursions (8.181), autodiff (8.14), numberroots (8.113), taylorform (8.180)

8.88 integer

Name: integer

  keyword representing a machine integer type

Usage:

    integer : type type

Description:

  • integer represents the machine integer type for declarations of external procedures externalproc.

    Remark that in contrast to other indicators, type indicators like integer cannot be handled outside the externalproc context. In particular, they cannot be assigned to variables.

See also: externalproc (8.62), boolean (8.20), constant (8.28), function (8.71), list of (8.96), range (8.142), string (8.170), object (8.115)

8.89 integral

Name: integral

  computes an interval bounding the integral of a function on an interval.

Library name:

  sollya_obj_t sollya_lib_integral(sollya_obj_t, sollya_obj_t)

Usage:

    integral(f,I) : (function, range) → range

Parameters:

  • f is a function.
  • I is an interval.
integral(f,I) returns an interval J such that the exact value of the integral of f on I lies in J.

This command is safe but very inefficient. Use dirtyintegral if you just want an approximate value.

The result of this command depends on the global variable diam. The method used is the following: I is cut into intervals of length not greater than \( \delta \cdot |I| \) where \( \delta \) is the value of global variable diam. On each small interval J, an evaluation of f by interval is performed. The result is multiplied by the length of J. Finally all values are summed.

Example 1:

```plaintext
> sin(10);
-0.5440211088936981340474766185137728168364301291621
> integral(cos(x),[0;10]);
[-0.54710197983579690224097637163525943075698599257332;-0.540940151300131838481054088137337044053741191728]
> diam=1e-5;
> integral(cos(x),[0;10]);
[-0.54432915685955427101857780295936956775293876382777;-0.5437130640124996950803 9644221927489010425803173555]
```

See also: diam (8.38), dirtyintegral (8.43), prec (8.129)

8.90 isbound

Name: isbound

indicates whether a variable is bound or not.

Usage:

```plaintext
isbound(ident) : boolean
```

Parameters:

- `ident` is a name.

Description:

- `isbound(ident)` returns a boolean value indicating whether the name `ident` is used or not to represent a variable. It returns true when `ident` is the name used to represent the global variable or if the name is currently used to refer to a (possibly local) variable.

- When a variable is defined in a block and has not been defined outside, `isbound` returns true when called inside the block, and false outside. Note that `isbound` returns true as soon as a variable has been declared with `var`, even if no value is actually stored in it.

- If `ident1` is bound to a variable and if `ident2` refers to the global variable, the command `rename(ident2, ident1)` hides the value of `ident1` which becomes the global variable. However, if the global variable is again renamed, `ident1` gets its value back. In this case, `isbound(ident1)` returns true. If `ident1` was not bound before, `isbound(ident1)` returns false after that `ident1` has been renamed.

Example 1:
> isbound(x);
false
> isbound(f);
false
> isbound(g);
false
> f=sin(x);
> isbound(x);
true
> isbound(f);
true
> isbound(g);
false

Example 2:

> isbound(a);
false
> { var a; isbound(a); };
true
> isbound(a);
false

Example 3:

> f=sin(x);
> isbound(x);
true
> rename(x,y);
> isbound(x);
false

Example 4:

> x=1;
> f=sin(y);
> rename(y,x);
> f;
sin(x)
> x;
x
> isbound(x);
true
> rename(x,y);
> isbound(x);
true
> x;
1

See also: `rename` (8.150)

### 8.91 `isevaluable`

**Name:** `isevaluable`

- tests whether a function can be evaluated at a point

**Usage:**
**isevaluable***(function, constant) : (function, constant) → boolean

Parameters:
- *function* represents a function
- *constant* represents a constant point

Description:
- *isevaluable* applied to function *function* and a constant *constant* returns a boolean indicating whether or not a subsequent call to *evaluate* on the same function *function* and constant *constant* will produce a numerical result or NaN. This means *isevaluable* returns false iff *evaluate* will return NaN.
- The command *isevaluable* is now considered DEPRECATED in Sollya. As checks for NaNs are now possible in Sollya, the command *isevaluable* can be fully emulated with a call to *evaluate* and a couple of tests, as shown below in the last example.

Example 1:
```
> isevaluable(sin(pi * 1/x), 0.75);
true
> print(evaluate(sin(pi * 1/x), 0.75));
-0.86602540378443864676372317075293618347140262690518
```

Example 2:
```
> isevaluable(sin(pi * 1/x), 0.5);
true
> print(evaluate(sin(pi * 1/x), 0.5));
[-1.72986452514381269516508615031098129542836767991679e-12715;7.5941198201187963145069564314525661706039084390067e-12716]
```

Example 3:
```
> isevaluable(sin(pi * 1/x), 0);
true
> print(evaluate(sin(pi * 1/x), 0));
[-1;1]
```

Example 4:
```
> procedure isEvaluableEmulation(f, c) {
    return match evaluate(f, c) with
        NaN : (false)
        [NaN;NaN] : (false)
        default : (true);
    };
> isEvaluableEmulation(sin(pi * 1/x), 0.75);
true
> isEvaluableEmulation(sin(pi * 1/x), 0.5);
true
> isEvaluableEmulation(sin(pi * 1/x), 0);
true
```

See also: *evaluate* [8.55]
8.92  <=

Name: <=
less-than-or-equal-to operator

Library name:
sollya_obj_t sollya_lib_cmp_less_equal(sollya_obj_t, sollya_obj_t)

Usage:

    expr1 <= expr2 : (constant, constant) → boolean

Parameters:

• expr1 and expr2 represent constant expressions

Description:

• The operator <= evaluates to true iff its operands expr1 and expr2 evaluate to two floating-point numbers \(a_1\) respectively \(a_2\) with the global precision prec and \(a_1\) is less than or equal to \(a_2\). The user should be aware of the fact that because of floating-point evaluation, the operator <= is not exactly the same as the mathematical operation less-than-or-equal-to.

Example 1:

```
> 5 <= 4;
false
> 5 <= 5;
true
> 5 <= 6;
true
> exp(2) <= exp(1);
false
> log(1) <= exp(2);
true
```

Example 2:

```
> prec = 12;
The precision has been set to 12 bits.
> 16385.1 <= 16384.1;
true
```

See also: == (8.51), ! (8.110), >= (8.72), > (8.74), < (8.101), in (8.85), ! (8.112), & & (8.6), || (8.118), prec (8.129), max (8.103), min (8.106)

8.93  length

Name: length
computes the length of a list or string.

Library name:
sollya_obj_t sollya_lib_length(sollya_obj_t)

Usage:

    length(L) : list → integer
    length(s) : string → integer

Parameters:

• \(L\) is a list.
• \( s \) is a string.

**Description:**

• **length** returns the length of a list or a string, e.g. the number of elements or letters.
• The empty list or string have length 0. If \( L \) is an end-elliptic list, **length** returns \(+\text{Inf}\).

**Example 1:**

```plaintext
> length("Hello World!");
12
```

**Example 2:**

```plaintext
> length([1,...,5]);
5
```

**Example 3:**

```plaintext
> length([| |]);
0
```

**Example 4:**

```plaintext
> length([|1,2...|]);
@Inf@```

### 8.94 library

**Name:** **library**  
binds an external mathematical function to a variable in **Sollya**

**Library names:**

```c
sollya_obj_t sollya_lib_libraryfunction(sollya_obj_t, char *,
    int (*)(mpfi_t, mpfi_t, int))
sollya_obj_t sollya_lib_build_function_libraryfunction(sollya_obj_t, char *,
    int (*)(mpfi_t,
    mpfi_t, int))
```

**Usage:**

```plaintext
library(path) : string \rightarrow \text{function}
```

**Description:**

• The command **library** lets you extend the set of mathematical functions known to **Sollya**. By default, **Sollya** knows the most common mathematical functions such as \( \exp, \sin, \text{erf} \), etc. Within **Sollya**, these functions may be composed. This way, **Sollya** should satisfy the needs of a lot of users. However, for particular applications, one may want to manipulate other functions such as Bessel functions, or functions defined by an integral or even a particular solution of an ODE.

• **library** makes it possible to let **Sollya** know about new functions. In order to let it know, you have to provide an implementation of the function you are interested in. This implementation is a C file containing a function of the form:

```c
int my_ident(sollya_mpfi_t result, sollya_mpfi_t op, int n)
```

The semantic of this function is the following: it is an implementation of the function and its derivatives in interval arithmetic. \( \text{my\_ident}(\text{result}, I, n) \) shall store in \( \text{result} \) an enclosure of the image set of the \( n \)-th derivative of the function \( f \) over \( I \): \( f^{(n)}(I) \subseteq \text{result} \).
• The integer value returned by the function implementation currently has no meaning.

• You do not need to provide a working implementation for any \( n \). Most functions of Sollya requires a relevant implementation only for \( f, f' \) and \( f'' \). For higher derivatives, its is not so critical and the implementation may just store \([-\infty, +\infty]\) in result whenever \( n > 2 \).

• Note that you should respect somehow interval-arithmetic standards in your implementation: \texttt{result} has its own precision and you should perform the intermediate computations so that \texttt{result} is as tight as possible.

• You can include sollya.h in your implementation and use library functionalities of Sollya for your implementation. However, this requires to have compiled Sollya with \texttt{-fPIC} in order to make the Sollya executable code position independent and to use a system on with programs, using \texttt{dlopen} to open dynamic routines can dynamically open themselves.

• To bind your function into Sollya, you must use the same identifier as the function name used in your implementation file (\texttt{my_ident} in the previous example). Once the function code has been bound to an identifier, you can use a simple assignment to assign the bound identifier to yet another identifier. This way, you may use convenient names inside Sollya even if your implementation environment requires you to use a less convenient name.

• The dynamic object file whose name is given to \texttt{library} for binding of an external library function may also define a destructor function \texttt{int sollya_external_lib_close(void)}. If Sollya finds such a destructor function in the dynamic object file, it will call that function when closing the dynamic object file again. This happens when Sollya is terminated or when the current Sollya session is restarted using \texttt{restart}. The purpose of the destructor function is to allow the dynamically bound code to free any memory that it might have allocated before Sollya is terminated or restarted. The dynamic object file is not necessarily needed to define a destructor function. This ensure backward compatibility with older Sollya external library function object files. When defined, the destructor function is supposed to return an integer value indicating if an error has happened. Upon success, the destructor functions is to return a zero value, upon error a non-zero value.

Example 1:

```bash
> bashexecute("gcc -fPIC -Wall -c libraryexample.c -I$HOME/.local/include");
> bashexecute("gcc -shared -o libraryexample libraryexample.o -lgmp -lmpfr");
> myownlog = library("./libraryexample");
> evaluate(log(x), 2);
0.693147180559945309417232145817656807550013436024
> evaluate(myownlog(x), 2);
0.693147180559945309417232145817656807550013436024
```

See also: \texttt{function (8.71)}, \texttt{bashexecute (8.17)}, \texttt{externalproc (8.62)}, \texttt{externalplot (8.61)}, \texttt{diff (8.40)}, \texttt{evaluate (8.55)}, \texttt{libraryconstant (8.95)}

### 8.95 libraryconstant

**Name:** libraryconstant

binds an external mathematical constant to a variable in Sollya

**Library names:**

```
sollya_obj_t sollya_lib_libraryconstant(char *, void (*)(mpfr_t, mp_prec_t))
sollya_obj_t sollya_lib_build_function_libraryconstant(char *,
    void (*)(mpfr_t, mp_prec_t))
```

**Usage:**

```
libraryconstant(path) : string → function
```
The command `libraryconstant` lets you extend the set of mathematical constants known to Sollya. By default, the only mathematical constant known by Sollya is `pi`. For particular applications, one may want to manipulate other constants, such as Euler's gamma constant, for instance.

`libraryconstant` makes it possible to let Sollya know about new constants. In order to let it know, you have to provide an implementation of the constant you are interested in. This implementation is a C file containing a function of the form:

```c
void my_ident(mpfr_t result, mp_prec_t prec)
```

The semantic of this function is the following: it is an implementation of the constant in arbitrary precision. `my_ident(result, prec)` shall set the precision of the variable result to a suitable precision (the variable is assumed to be already initialized) and store in result an approximate value of the constant with a relative error not greater than $2^{1-\text{prec}}$. More precisely, if $c$ is the exact value of the constant, the value stored in result should satisfy

$$ |\text{result} - c| \leq |c| 2^{1-\text{prec}}. $$

- You can include sollya.h in your implementation and use library functionalities of Sollya for your implementation. However, this requires to have compiled Sollya with `-fPIC` in order to make the Sollya executable code position independent and to use a system on with programs, using `dlopen` to open dynamic routines can dynamically open themselves.

- To bind your constant into Sollya, you must use the same identifier as the function name used in your implementation file (`my_ident` in the previous example). Once the function code has been bound to an identifier, you can use a simple assignment to assign the bound identifier to yet another identifier. This way, you may use convenient names inside Sollya even if your implementation environment requires you to use a less convenient name.

- Once your constant is bound, it is considered by Sollya as an infinitely accurate constant (i.e. a 0-ary function, exactly like `pi`).

- The dynamic object file whose name is given to `libraryconstant` for binding of an external library constant may also define a destructor function `int sollya_external_lib_close(void)`. If Sollya finds such a destructor function in the dynamic object file, it will call that function when closing the dynamic object file again. This happens when Sollya is terminated or when the current Sollya session is restarted using `restart`. The purpose of the destructor function is to allow the dynamically bound code to free any memory that it might have allocated before Sollya is terminated or restarted. The dynamic object file is not necessarily needed to define a destructor function. This ensure backward compatibility with older Sollya external library function object files. When defined, the destructor function is supposed to return an integer value indicating if an error has happened. Upon success, the destructor functions is to return a zero value, upon error a non-zero value.

Example 1:
bashexecute("gcc -fPIC -Wall -c libraryconstantexample.c -I$HOME/.local/include");
bashexecute("gcc -shared -o libraryconstantexample libraryconstantexample.o -l
 gmp -lmpfr");
euler_gamma = libraryconstant("./libraryconstantexample");
> prec = 20!
> euler_gamma;
0.577215
> prec = 100!
> euler_gamma;
0.577215664901532860606512090082
> midpointmode = on;
Midpoint mode has been activated.
> [euler_gamma];
0.57721566490153286060651209008~2/4~

See also: `bashexecute` (8.17), `externalproc` (8.62), `externalplot` (8.61), `pi` (8.121), `library` (8.94), `evaluate` (8.55), `implementconstant` (8.83)

8.96  list of
Name: list of
    keyword used in combination with a type keyword

Description:

- list of is used in combination with one of the following keywords for indicating lists of the respective type in declarations of external procedures using `externalproc`: boolean, constant, function, integer, range and string.

See also: `externalproc` (8.62), `boolean` (8.20), `constant` (8.28), `function` (8.71), `integer` (8.88), `range` (8.142), `string` (8.170), `object` (8.115)

8.97  log
Name: log
    natural logarithm.

Library names:
sollya_obj_t sollya_lib_log(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_log(sollya_obj_t)
#define SOLLYA_LOG(x) sollya_lib_build_function_log(x)

Description:

- log is the natural logarithm defined as the inverse of the exponential function: log(y) is the unique real number x such that exp(x) = y.
- It is defined only for y ∈ [0; +∞).

See also: `exp` (8.57), `log2` (8.100), `log10` (8.98)

8.98  log10
Name: log10
    decimal logarithm.

Library names:
sollya_obj_t sollya_lib_log10(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_log10(sollya_obj_t)
#define SOLLYA_LOG10(x) sollya_lib_build_function_log10(x)

Description:

- **log10** is the decimal logarithm defined by: \( \log_{10}(x) = \log(x) / \log(10) \).
- It is defined only for \( x \in [0; +\infty] \).

See also: log \((8.97)\), log2 \((8.100)\)

8.99  log1p

Name: **log1p**
translated logarithm.

Library names:
- sollya_obj_t sollya_lib_log1p(sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_log1p(sollya_obj_t)
- #define SOLLYA_LOG1P(x) sollya_lib_build_function_log1p(x)

Description:

- **log1p** is the function defined by \( \log_{1+}(x) = \log(1 + x) \).
- It is defined only for \( x \in [-1; +\infty] \).

See also: log \((8.97)\)

8.100  log2

Name: **log2**
binary logarithm.

Library names:
- sollya_obj_t sollya_lib_log2(sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_log2(sollya_obj_t)
- #define SOLLYA_LOG2(x) sollya_lib_build_function_log2(x)

Description:

- **log2** is the binary logarithm defined by: \( \log_{2}(x) = \log(x) / \log(2) \).
- It is defined only for \( x \in [0; +\infty] \).

See also: log \((8.97)\), log10 \((8.98)\)

8.101  <

Name: **<**
less-than operator

Library name:
- sollya_obj_t sollya_lib_cmp_less(sollya_obj_t, sollya_obj_t)

Usage:

\( expr1 < expr2 : (\text{constant, constant}) \rightarrow \text{boolean} \)

Parameters:

- \( expr1 \) and \( expr2 \) represent constant expressions

Description:
The operator < evaluates to true iff its operands expr1 and expr2 evaluate to two floating-point numbers \( a_1 \) respectively \( a_2 \) with the global precision prec and \( a_1 \) is less than \( a_2 \). The user should be aware of the fact that because of floating-point evaluation, the operator < is not exactly the same as the mathematical operation less-than.

**Example 1:**

```plaintext
> 5 < 4;
false
> 5 < 5;
false
> 5 < 6;
true
> exp(2) < exp(1);
false
> log(1) < exp(2);
true
```

**Example 2:**

```plaintext
> prec = 12;
The precision has been set to 12 bits.
> 16384.1 < 16385.1;
false
```

See also: == (8.51), != (8.110), > (8.72), >= (8.74), <= (8.92), in (8.85), | (8.112), && (8.6), || (8.118), prec (8.129), max (8.103), min (8.106)

### 8.102 mantissa

**Name:** mantissa

returns the integer mantissa of a number.

**Library name:**

```
sollya_obj_t sollya_lib_mantissa(sollya_obj_t)
```

**Usage:**

```
mantissa(x) : constant → integer
```

**Parameters:**

- \( x \) is a dyadic number.

**Description:**

- \( \text{mantissa}(x) \) is by definition \( x \) if \( x \) equals 0, NaN, or Inf.
- If \( x \) is not zero, it can be uniquely written as \( x = m \cdot 2^e \) where \( m \) is an odd integer and \( e \) is an integer. \( \text{mantissa}(x) \) returns \( m \).

**Example 1:**

```plaintext
> a=round(Pi,20,RN);
> e=exponent(a);
> m=mantissa(a);
> m;
411775
> a-m*2^e;
0
```

See also: exponent (8.60), precision (8.130)
8.103 max

Name: max
determines which of given constant expressions has maximum value

Library names:
  sollya_obj_t sollya_lib_max(sollya_obj_t, ...)
sollya_obj_t sollya_lib_v_max(sollya_obj_t, va_list)

Usage:
  \texttt{max}(expr1,expr2,...,exprn) : (constant, constant, ..., constant) \rightarrow constant
  \texttt{max}(l) : list \rightarrow constant

Parameters:
  \begin{itemize}
    \item \emph{expr} are constant expressions.
    \item \emph{l} is a list of constant expressions.
  \end{itemize}

Description:
  \begin{itemize}
    \item \emph{max} determines which of a given set of constant expressions \emph{expr} has maximum value. To do so, \emph{max} tries to increase the precision used for evaluation until it can decide the ordering or some maximum precision is reached. In the latter case, a warning is printed indicating that there might actually be another expression that has a greater value.
    \item Even though \emph{max} determines the maximum expression by evaluation, it returns the expression that is maximum as is, i.e. as an expression tree that might be evaluated to any accuracy afterwards.
    \item \emph{max} can be given either an arbitrary number of constant expressions in argument or a list of constant expressions. The list however must not be end-elliptic.
    \item Users should be aware that the behavior of \emph{max} follows the IEEE 754-2008 standard with respect to NaNs. In particular, \emph{max} evaluates to NaN if and only if all arguments of \emph{max} are NaNs. This means that NaNs may disappear during computations.
  \end{itemize}

Example 1:
\begin{verbatim}
> max(1,2,3,exp(5),log(0.25));
1.4841315910257660342115580040552279623487667593878e2
> max(17);
17
\end{verbatim}

Example 2:
\begin{verbatim}
> l = [|1,2,3,exp(5),log(0.25)|];
> max(l);
1.4841315910257660342115580040552279623487667593878e2
\end{verbatim}

Example 3:
\begin{verbatim}
> print(max(exp(17),sin(62)));
exp(17)
\end{verbatim}

Example 4:
\begin{verbatim}
> verbosity = 1!;
> print(max(17 + log2(13)/log2(9),17 + log(13)/log(9)));
Warning: the tool is unable to decide a maximum computation by evaluation even though faithful evaluation of the terms has been possible. The terms will be considered to be equal.
17 + log2(13) / log2(9)
\end{verbatim}

See also: min (8.106), \texttt{==} (8.51), \texttt{!=} (8.110), \texttt{>=} (8.72), \texttt{> (8.73)}, \texttt{<} (8.101), \texttt{<=} (8.92), \texttt{in} (8.85), inf (8.86), sup (8.173)
8.104  mid

Name: mid
gives the middle of an interval.

Library name:
sollya_obj_t sollya_lib_mid(sollya_obj_t)

Usage:

\[
\text{mid}(I) : \text{range} \rightarrow \text{constant}
\]
\[
\text{mid}(x) : \text{constant} \rightarrow \text{constant}
\]

Parameters:

- \( I \) is an interval.
- \( x \) is a real number.

Description:

- Returns the middle of the interval \( I \). If the middle is not exactly representable at the current precision, the value is returned as an unevaluated expression.
- When called on a real number \( x \), \text{mid} behaves like the identity.

Example 1:

\[
\begin{align*}
> \text{mid}([1; 3]); \\
2 \\
> \text{mid}(17);
17
\end{align*}
\]

See also: \text{inf} \( \text{8.86} \), \text{sup} \( \text{8.173} \)

8.105  midpointmode

Name: midpointmode
global variable controlling the way intervals are displayed.

Library names:

- void sollya_lib_set_midpointmode_and_print(sollya_obj_t)
- void sollya_lib_set_midpointmode(sollya_obj_t)
- sollya_obj_t sollya_lib_get_midpointmode()

Usage:

\[
\text{midpointmode} = \text{activation value} : \text{on|off} \rightarrow \text{void}
\]
\[
\text{midpointmode} = \text{activation value} ! : \text{on|off} \rightarrow \text{void}
\]
\[
\text{midpointmode} : \text{on|off}
\]

Parameters:

- \text{activation value} enables or disables the mode.

Description:

- \text{midpointmode} is a global variable. When its value is \text{off}, intervals are displayed as usual (in the form \([a; b])\). When its value is \text{on}, and if \(a\) and \(b\) have the same first significant digits, the interval is displayed in a way that lets one immediately see the common digits of the two bounds.
- This mode is supported only with \text{display} set to \text{decimal}. In other modes of display, \text{midpointmode} value is simply ignored.
Example 1:

```plaintext
> a = round(Pi,30,RD);
> b = round(Pi,30,RU);
> d = [a,b];
> d;
[3.1415926516056060791015625;3.1415926553308963775634765625]
> midpointmode=on!;
> d;
0.314159265~1/6~e1
```

See also: on [8.117], off [8.116], roundingwarnings [8.158], display [8.45], decimal [8.34]

8.106 min

Name: **min**

determines which of given constant expressions has minimum value

Library names:

- `sollya_obj_t sollya_lib_min(sollya_obj_t, ...)`
- `sollya_obj_t sollya_lib_v_min(sollya_obj_t, va_list)`

Usage:

```
min(expr1,expr2,...,exprn) : (constant, constant, ..., constant) → constant
min(l) : list → constant
```

Parameters:

- `expr` are constant expressions.
- `l` is a list of constant expressions.

Description:

- **min** determines which of a given set of constant expressions `expr` has minimum value. To do so, **min** tries to increase the precision used for evaluation until it can decide the ordering or some maximum precision is reached. In the latter case, a warning is printed indicating that there might actually be another expression that has a lesser value.

- Even though **min** determines the minimum expression by evaluation, it returns the expression that is minimum as is, i.e. as an expression tree that might be evaluated to any accuracy afterwards.

- **min** can be given either an arbitrary number of constant expressions in argument or a list of constant expressions. The list however must not be end-elliptic.

- Users should be aware that the behavior of **min** follows the IEEE 754-2008 standard with respect to NaNs. In particular, **min** evaluates to NaN if and only if all arguments of **min** are NaNs. This means that NaNs may disappear during computations.

Example 1:

```
> min(1,2,3,exp(5),log(0.25));
-1.3862943611198906188344642429163531361510002687205
> min(17);
17
```

Example 2:

```
> l = [[1,2,3,exp(5),log(0.25)]];
> min(l);
-1.3862943611198906188344642429163531361510002687205
```
Example 3:

```plaintext
> print(min(exp(17),sin(62)));

sin(62)
```

Example 4:

```plaintext
> verbosity = 1;
> print(min(17 + log2(13)/log2(9),17 + log(13)/log(9)));

Warning: the tool is unable to decide a minimum computation by evaluation even though faithful evaluation of the terms has been possible. The terms will be considered to be equal.

17 + log(13) / log(9)
```

See also: `max` (8.103), `==` (8.51), `!=` (8.110), `>=` (8.72), `>` (8.74), `<` (8.101), `<=` (8.92), `in` (8.85), `inf` (8.86), `sup` (8.173)

8.107 −

Name: − subtraction function

Library names:

- `sollya_obj_t sollya_lib_sub(sollya_obj_t, sollya_obj_t)`
- `sollya_obj_t sollya_lib_build_function_sub(sollya_obj_t, sollya_obj_t)`
- `#define SOLLYA_SUB(x,y) sollya_lib_build_function_sub((x), (y))`
- `sollya_obj_t sollya_lib_neg(sollya_obj_t)`
- `sollya_obj_t sollya_lib_build_function_neg(sollya_obj_t)`
- `#define SOLLYA_NEG(x) sollya_lib_build_function_neg(x)`

Usage:

- `function1 − function2 : (function, function) → function`
- `interval1 − interval2 : (range, range) → range`
- `interval1 − constant : (range, constant) → range`
- `interval1 − constant : (constant, range) → range`
- `− function1 : function → function`
- `− interval1 : range → range`

Parameters:

- `function1` and `function2` represent functions
- `interval1` and `interval2` represent intervals (ranges)
- `constant` represents a constant or constant expression

Description:

- − represents the subtraction (function) on reals. The expression `function1 − function2` stands for the function composed of the subtraction function and the two functions `function1` and `function2`, where `function1` is the subtrahend and `function2` the subtractor.
- − can be used for interval arithmetic on intervals (ranges). − will evaluate to an interval that safely encompasses all images of the subtraction function with arguments varying in the given intervals. Any combination of intervals with intervals or constants (resp. constant expressions) is supported. However, it is not possible to represent families of functions using an interval as one argument and a function (varying in the free variable) as the other one.
- − stands also for the negation function.
Example 1:
\[
\text{> 5 - 2;}
\]
\[
3
\]

Example 2:
\[
\text{> x - 2;}
\]
\[
-2 + x
\]

Example 3:
\[
\text{> x - x;}
\]
\[
0
\]

Example 4:
\[
\text{> diff(sin(x) - exp(x));}
\]
\[
cos(x) - \exp(x)
\]

Example 5:
\[
\text{> [1;2] - [3;4];}
\]
\[
[-3;-1]
\]
\[
\text{> [1;2] - 17;}
\]
\[
[-16;-15]
\]
\[
\text{> 13 - [-4;17];}
\]
\[
[-4;17]
\]

Example 6:
\[
\text{> -exp(x);}
\]
\[
-exp(x)
\]
\[
\text{> -13;}
\]
\[
-13
\]
\[
\text{> -[13;17];}
\]
\[
[-17;-13]
\]

See also: + (8.123), ∗ (8.108), / (8.46), ^ (8.127)

8.108 ∗

Name: ∗
multiplication function

Library names:

```c
sollya_obj_t sollya_lib_mul(sollya_obj_t, sollya_obj_t)
sollya_obj_t sollya_lib_build_function_mul(sollya_obj_t, sollya_obj_t)
#define SOLLYA_MUL(x,y) sollya_lib_build_function_mul((x), (y))
```

Usage:

```c
function1 ∗ function2 : (function, function) → function
interval1 ∗ interval2 : (range, range) → range
interval1 ∗ constant : (range, constant) → range
interval1 ∗ constant : (constant, range) → range
```

Parameters:

- *function1* and *function2* represent functions
• `interval1` and `interval2` represent intervals (ranges)
• `constant` represents a constant or constant expression

Description:
• `*` represents the multiplication (function) on reals. The expression `function1 * function2` stands for the function composed of the multiplication function and the two functions `function1` and `function2`.
• `*` can be used for interval arithmetic on intervals (ranges). `*` will evaluate to an interval that safely encompasses all images of the multiplication function with arguments varying in the given intervals. Any combination of intervals with intervals or constants (resp. constant expressions) is supported. However, it is not possible to represent families of functions using an interval as one argument and a function (varying in the free variable) as the other one.

Example 1:
```
> 5 * 2;
10
```

Example 2:
```
> x * 2;
x * 2
```

Example 3:
```
> x * x;
x^2
```

Example 4:
```
> diff(sin(x) * exp(x));
\sin(x) * \exp(x) + \exp(x) * \cos(x)
```

Example 5:
```
> [1;2] * [3;4];
[3;8]
> [1;2] * 17;
[17;34]
> 13 * [-4;17];
[-52;221]
```

See also: `+ (8.123)`, `- (8.107)`, `/ (8.46)`, `ˆ (8.127)`

8.109 nearestint

Name: nearestint

the function mapping the reals to the integers nearest to them.

Library names:
sollya_obj_t sollya_lib_nearestint(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_nearestint(sollya_obj_t)
#define SOLLYA_NEARESTINT(x) sollya_lib_build_function_nearestint(x)

Description:
• `nearestint` is defined as usual: `nearestint(x)` is the integer nearest to `x`, with the special rule that the even integer is chosen if there exist two integers equally near to `x`.
• `nearestint` is defined for every real number `x`.

See also: `ceil (8.22)`, `floor (8.68)`, `round (8.155)`, `RN (8.154)`
Name: !=

negated equality test operator

Library name:
sollya_obj_t sollya_lib_cmp_not_equal(sollya_obj_t, sollya_obj_t)

Usage:

expr1 != expr2 : (any type, any type) → boolean

Parameters:

• expr1 and expr2 represent expressions

Description:

• The operator != evaluates to true iff its operands expr1 and expr2 are syntactically unequal and both different from error or constant expressions that are not constants and that evaluate to two different floating-point number with the global precision prec. The user should be aware of the fact that because of floating-point evaluation, the operator != is not exactly the same as the negation of the mathematical equality.

Note that the expressions !(expr1 != expr2) and expr1 == expr2 do not evaluate to the same boolean value. See error for details.

Example 1:

> "Hello" != "Hello";
false
> "Hello" != "Salut";
true
> "Hello" != 5;
true
> 5 + x != 5 + x;
false

Example 2:

> 1 != exp(0);
false
> asin(1) * 2 != pi;
false
> exp(5) != log(4);
true

Example 3:

> sin(pi/6) != 1/2 * sqrt(3);
true

Example 4:

> prec = 12;
The precision has been set to 12 bits.
> 16384.1 != 16385.1;
false

Example 5:

> error != error;
false

See also: == (8.51), >= (8.74), <= (8.72), < (8.92), <= (8.101), in (8.85), ! (8.112), && (8.6), || (8.118), error (8.54), prec (8.129)

143
8.111  nop
Name:  nop
    no operation
Usage:

nop : void → void
nop() : void → void
nop(n) : integer → void

Description:

- The command nop does nothing. This means it is an explicit parse element in the Sollya language that finally does not produce any result or side-effect.

- The command nop may take an optional positive integer argument n. The argument controls how much (useless) multiprecision floating-point multiplications Sollya performs while doing nothing. With this behaviour, nop can be used for calibration of timing tests.

- The keyword nop is implicit in some procedure definitions. Procedures without imperative body get parsed as if they had an imperative body containing one nop statement.

Example 1:

> nop;

Example 2:

> nop(100);

Example 3:

> succ = proc(n) { return n + 1; };
> succ;
proc(n)
{
    nop;
    return (n) + (1);
}
> succ(5);
6

See also: proc [8.137], time [8.183]

8.112  !
Name:  !
    boolean NOT operator
Library name:
    sollya_obj_t sollya_lib_negate(sollya_obj_t)
Usage:

! expr : boolean → boolean

Parameters:

- expr represents a boolean expression

Description:
• ! evaluates to the boolean NOT of the boolean expression expr. ! expr evaluates to true iff expr does not evaluate to true.

Example 1:

> ! false;
true

Example 2:

> !(1 == exp(0));
false

See also: && (8.6), || (8.118)

8.113 numberroots

Name: numberroots

Computes the number of roots of a polynomial in a given range.

Library name:

sollya_obj_t sollya_lib_numberroots(sollya_obj_t, sollya_obj_t)

Usage:

numberroots($p$, $I$) : ($function$, $range$) → $integer$

Parameters:

• $p$ is a polynomial.
• $I$ is an interval.

Description:

• numberroots rigorously computes the number of roots of polynomial the $p$ in the interval $I$. The technique used is Sturm’s algorithm. The value returned is not just a numerical estimation of the number of roots of $p$ in $I$: it is the exact number of roots.

• The command findzeros computes safe enclosures of all the zeros of a function, without forgetting any, but it is not guaranteed to separate them all in distinct intervals. numberroots is more accurate since it guarantees the exact number of roots. However, it does not compute them. It may be used, for instance, to certify that findzeros did not put two distinct roots in the same interval.

• Multiple roots are counted only once.

• The interval $I$ must be bounded. The algorithm cannot handle unbounded intervals. Moreover, the interval is considered as a closed interval: if one (or both) of the endpoints of $I$ are roots of $p$, they are counted.

• The argument $p$ can be any expression, but if Sollya fails to prove that it is a polynomial an error is produced. Also, please note that if the coefficients of $p$ or the endpoints of $I$ are not exactly representable, they are first numerically evaluated, before the algorithm is used. In that case, the counted number of roots corresponds to the rounded polynomial on the rounded interval and not to the exact parameters given by the user. A warning is displayed to inform the user.

Example 1:

> numberroots(1+x-x^2, [1,2]);
1
> findzeros(1+x-x^2, [1,2]);
[[[1.617919921875;1.6180419921875]]]
Example 2:

```latex
> numberroots((1+x)*(1-x), [-1,1]);
2
> numberroots(x^2, [-1,1]);
1
```

Example 3:

```latex
> verbosity = 1!
> numberroots(x-pi, [0,4]);
Warning: the 0th coefficient of the polynomial is neither a floating point
constant nor can be evaluated without rounding to a floating point constant.
Will faithfully evaluate it with the current precision (165 bits)
1
```

Example 4:

```latex
> verbosity = 1!
> numberroots(1+x-x^2, [0, @Inf@]);
Warning: the given interval must have finite bounds.
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
> numberroots(exp(x), [0, 1]);
Warning: the given function must be a polynomial in this context.
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
```

See also: `dirtyfindzeros [8.41]`, `findzeros [8.65]`

### 8.114 numerator

**Name:** numerator

Gives the numerator of an expression

**Library name:**

```
sollya_obj_t sollya_lib_numerator(sollya_obj_t)
```

**Usage:**

```
numerator(expr) : function → function
```

**Parameters:**

- `expr` represents an expression

**Description:**

- If `expr` represents a fraction `expr1/expr2`, `numerator(expr)` returns the numerator of this fraction, i.e. `expr1`.

  If `expr` represents something else, `numerator(expr)` returns the expression itself, i.e. `expr`.

  Note that for all expressions `expr`, `numerator(expr) / denominator(expr)` is equal to `expr`.

**Example 1:**
Example 2:

```
> numerator(exp(x));
exp(x)
```

Example 3:

```
> a = 5/3;
> b = numerator(a)/denominator(a);
> print(a);
5 / 3
> print(b);
5 / 3
```

Example 4:

```
> a = exp(x/3);
> b = numerator(a)/denominator(a);
> print(a);
exp(x / 3)
> print(b);
exp(x / 3)
```

See also: `denominator` (8.37), `rationalmode` (8.144)

### 8.115 object

**Name:** object

Keyword representing a Sollya object type

**Usage:**

```
object : type type
```

**Description:**

- object represents the Sollya object type for declarations of external procedures externalproc.

Remark that in contrast to other indicators, type indicators like object cannot be handled outside the externalproc context. In particular, they cannot be assigned to variables.

See also: externalproc (8.62), boolean (8.20), constant (8.28), function (8.71), list of (8.96), range (8.142), string (8.170), integer (8.88)

### 8.116 off

**Name:** off

Special value for certain global variables.

**Library names:**

```
sollya_obj_t sollya_lib_off()
int sollya_lib_is_off(sollya_obj_t)
```

**Description:**

- off is a special value used to deactivate certain functionalities of Sollya.

- As any value it can be affected to a variable and stored in lists.

147
Example 1:

```plaintext
> canonical=on;
Canonical automatic printing output has been activated.
> p=1+x+x^2;
> mode=off;
> p;
1 + x + x^2
> canonical=mode;
Canonical automatic printing output has been deactivated.
> p;
1 + x * (1 + x)
```

See also: on (8.117), autosimplify (8.15), canonical (8.21), timing (8.184), fullparentheses (8.70), midpointmode (8.105), rationalmode (8.144), roundingwarnings (8.158), timing (8.184), dieonerrormode (8.39)

### 8.117 on

Name: on

- special value for certain global variables.

Library names:

- sollya_obj_t sollya_lib_on()
- int sollya_lib_is_on(sollya_obj_t)

Description:

- **on** is a special value used to activate certain functionalities of Sollya.
- As any value it can be affected to a variable and stored in lists.

Example 1:

```plaintext
> p=1+x+x^2;
> mode=on;
> p;
1 + x + x^2
> canonical=mode;
Canonical automatic printing output has been activated.
> p;
1 + x * (1 + x)
```

See also: off (8.116), autosimplify (8.15), canonical (8.21), timing (8.184), fullparentheses (8.70), midpointmode (8.105), rationalmode (8.144), roundingwarnings (8.158), timing (8.184), dieonerrormode (8.39)

### 8.118 ||

Name: **

- boolean OR operator

Library name:

- sollya_obj_t sollya_lib_or(sollya_obj_t, sollya_obj_t)

Usage:

```plaintext
expr1 || expr2 : (boolean, boolean) → boolean
```

Parameters:
• `expr1` and `expr2` represent boolean expressions

Description:

• `||` evaluates to the boolean OR of the two boolean expressions `expr1` and `expr2`. `||` evaluates to true if at least one of `expr1` or `expr2` evaluates to true.

Example 1:

```plaintext
> false || false;
false
```

Example 2:

```plaintext
> (1 == exp(0)) || (0 == log(1));
true
```

See also: `&&` [8.6], `!` [8.112]

### 8.119 `parse`

Name: `parse`

parses an expression contained in a string

Library name:

```plaintext
sollya_obj_t sollya_lib_parse(sollya_obj_t)
```

Usage:

```plaintext
parse(string) : string → function | error
```

Parameters:

• `string` represents a character sequence

Description:

• `parse(string)` parses the character sequence `string` containing an expression built on constants and base functions.

  If the character sequence does not contain a well-defined expression, a warning is displayed indicating a syntax error and `parse` returns a `error` of type `error`.

• The character sequence to be parsed by `parse` may contain commands that return expressions, including `parse` itself. Those commands get executed after the string has been parsed. `parse(string)` will return the expression computed by the commands contained in the character sequence `string`.

Example 1:

```plaintext
> parse("exp(x)");
exp(x)
```

Example 2:

```plaintext
> text = "remez(exp(x),5,[-1;1])";
> print("The string", text, "gives", parse(text));
The string remez(exp(x),5,[-1;1]) gives 8.7381909882756203676868315731687604903964388498642e-3 * x^-5 + 4.3793696379596015478233171265365272893795005588381e-2 * x^-4 + 0.16642465614952768185129433844012193925654065755905 * x^-3 + 0.4991969926 * x^-2 + 1.0000383465059981546634006805821490154087808492516 * x + 1.00004475029559502606203712816558243384077522932213
```
Example 3:

```bash
> verbosity = 1!
> parse("5 + * 3");
Warning: syntax error, unexpected *. Will try to continue parsing (expecting ";" ) . May leak memory.
Warning: the string "5 + * 3" could not be parsed by the miniparser.
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
```

See also: execute (8.56), readfile (8.146), print (8.132), error (8.54), dieonerrormode (8.39)

### 8.120 perturb

**Name:** perturb  
indicates random perturbation of sampling points for `externalplot`

**Library names:**
- `sollya_obj_t sollya_lib_perturb()`  
- `int sollya_lib_is_perturb(sollya_obj_t)`

**Usage:**

```
perturb : perturb
```

**Description:**
- The use of `perturb` in the command `externalplot` enables the addition of some random noise around each sampling point in `externalplot`.  
  See `externalplot` for details.

**Example 1:**

```bash
> bashexecute("gcc -fPIC -c externalplotexample.c");
> bashexecute("gcc -shared -o externalplotexample externalplotexample.o -lgmp -l
mpfr");
> externalplot("./externalplotexample",relative,exp(x),[-1/2;1/2],12,perturb);
```

See also: `externalplot` (8.61), `absolute` (8.2), `relative` (8.148), `bashexecute` (8.17)

### 8.121 pi

**Name:** pi  
the constant $\pi$.

**Library names:**
- `sollya_obj_t sollya_lib_pi()`  
- `int sollya_lib_is_pi(sollya_obj_t)`  
- `sollya_obj_t sollya_lib_build_function_pi()`  
- `#define SOLLYA_PI (sollya_lib_build_function_pi())`

**Description:**
- $\pi$ is the constant $\pi$, defined as half the period of sine and cosine.
- In Sollya, $\pi$ is considered a 0-ary function. This way, the constant is not evaluated at the time of its definition but at the time of its use. For instance, when you define a constant or a function relating to $\pi$, the current precision at the time of the definition does not matter. What is important is the current precision when you evaluate the function or the constant value.
Remark that when you define an interval, the bounds are first evaluated and then the interval is defined. In this case, \( \pi \) will be evaluated as any other constant value at the definition time of the interval, thus using the current precision at this time.

Example 1:

```plaintext
> verbosity=1!; prec=12!;
> a = 2*pi;
> a;
Warning: rounding has happened. The value displayed is a faithful rounding to 12 bits of the true result.
6.283
> prec=20!;
> a;
Warning: rounding has happened. The value displayed is a faithful rounding to 20 bits of the true result.
6.283187
```

Example 2:

```plaintext
> display=binary;
Display mode is binary numbers.
> prec=12!;
> d = [pi; 5];
> d;
[1.1001001_2 * 2^(1);1.01_2 * 2^(2)]
> prec=20!;
> d;
[1.1001001_2 * 2^(1);1.01_2 * 2^(2)]
```

See also: \( \cos \) (8.29), \( \sin \) (8.165), \( \tan \) (8.177), \( \text{asin} \) (8.10), \( \text{acos} \) (8.4), \( \text{atan} \) (8.12), \( \text{evaluate} \) (8.55), \( \text{prec} \) (8.129), \( \text{libraryconstant} \) (8.95)

8.122 plot

Name: plot
plots one or several functions

Library names:
void sollya_lib_plot(sollya_obj_t, sollya_obj_t, ...)
void sollya_lib_v_plot(sollya_obj_t, sollya_obj_t, va_list)

Usage:

```plaintext
plot(f1, ... , fn, I) : (function, ... , function, range) \to void
plot(f1, ... , fn, I, file, name) : (function, ... , function, range, file, string) \to void
plot(f1, ... , fn, I, postscript, name) : (function, ... , function, range, postscript, string) \to void
plot(f1, ... , fn, I, postscriptfile, name) : (function, ... , function, range, postscriptfile, string) \to void
plot(L, I) : (list, range) \to void
plot(L, I, file, name) : (list, range, file, string) \to void
plot(L, I, postscript, name) : (list, range, postscript, string) \to void
plot(L, I, postscriptfile, name) : (list, range, postscriptfile, string) \to void
```

Parameters:

- \( f1, ..., fn \) are functions to be plotted.
- \( L \) is a list of functions to be plotted.
- \( I \) is the interval where the functions have to be plotted.
- **name** is a string representing the name of a file.

**Description:**

- This command plots one or several functions $f_1, \ldots, f_n$ on an interval $I$. Functions can be either given as parameters of `plot` or as a list $L$ which elements are functions. The functions are drawn on the same plot with different colors.

- If $L$ contains an element that is not a function (or a constant), an error occurs.

- `plot` relies on the value of global variable **points**. Let $n$ be the value of this variable. The algorithm is the following: each function is evaluated at $n$ evenly distributed points in $I$. At each point, the computed value is a faithful rounding of the exact value with a sufficiently high precision. Each point is finally plotted. This should avoid numerical artefacts such as critical cancellations.

- You can save the function plot either as a data file or as a postscript file.

- If you use argument `file` with a string **name**, **Sollya** will save a data file called `name.dat` and a gnuplot directives file called `name.p`. Invoking gnuplot on `name.p` will plot the data stored in `name.dat`.

- If you use argument `postscript` with a string **name**, **Sollya** will save a postscript file called `name.eps` representing your plot.

- If you use argument `postscriptfile` with a string **name**, **Sollya** will produce the corresponding `name.dat`, `name.p` and `name.eps`.

- This command uses gnuplot to produce the final plot. If your terminal is not graphic (typically if you use **Sollya** through ssh without -X) gnuplot should be able to detect that and produce an ASCII-art version on the standard output. If it is not the case, you can either store the plot in a postscript file to view it locally, or use `asciiplot` command.

- If every function is constant, `plot` will not plot them but just display their value.

- If the interval is reduced to a single point, `plot` will just display the value of the functions at this point.

**Example 1:**

```
> plot(sin(x),0,cos(x),[-Pi,Pi]);
```

**Example 2:**

```
> plot(sin(x),0,cos(x),[-Pi,Pi],postscriptfile,"plotSinCos");
```

**Example 3:**

```
> plot(exp(0), sin(1), [0;1]);
1
0.84147098480789650665250232163029899962256306079837
```

**Example 4:**

```
> plot(sin(x), cos(x), [1;1]);
0.84147098480789650665250232163029899962256306079837
0.540302305868139717400936667442976603733233142061792
```

See also: **externalplot** [8.61], **asciiplot** [8.9], **file** [8.64], **postscript** [8.125], **postscriptfile** [8.126], **points** [8.124]
+  

Name: +
addition function

Library names:

- sollya_obj_t sollya_lib_add(sollya_obj_t, sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_add(sollya_obj_t, sollya_obj_t)

#define SOLLYA_ADD(x,y) sollya_lib_build_function_add((x), (y))

Usage:

- \textit{function1} + \textit{function2} : (\text{function, function}) \rightarrow \text{function}
- interval1 + interval2 : (\text{range, range}) \rightarrow \text{range}
- interval1 + constant : (\text{range, constant}) \rightarrow \text{range}
- interval1 + constant : (\text{constant, range}) \rightarrow \text{range}

Parameters:

- \textit{function1} and \textit{function2} represent functions
- \textit{interval1} and \textit{interval2} represent intervals (ranges)
- \textit{constant} represents a constant or constant expression

Description:

- + represents the addition (function) on reals. The expression \textit{function1} + \textit{function2} stands for the function composed of the addition function and the two functions \textit{function1} and \textit{function2}.
- + can be used for interval arithmetic on intervals (ranges). + will evaluate to an interval that safely encompasses all images of the addition function with arguments varying in the given intervals. Any combination of intervals with intervals or constants (resp. constant expressions) is supported. However, it is not possible to represent families of functions using an interval as one argument and a function (varying in the free variable) as the other one.

Example 1:

\begin{verbatim}
> 1 + 2;
3
\end{verbatim}

Example 2:

\begin{verbatim}
> x + 2;
2 + x
\end{verbatim}

Example 3:

\begin{verbatim}
> x + x;
x * 2
\end{verbatim}

Example 4:

\begin{verbatim}
> diff(sin(x) + exp(x));
\cos(x) + \exp(x)
\end{verbatim}

Example 5:

\begin{verbatim}
> [1;2] + [3;4];
[4;6]
> [1;2] + 17;
[18;19]
> 13 + [-4;17];
[9;30]
\end{verbatim}

See also: − \(8.107\), * \(8.108\), / \(8.46\), ^ \(8.127\)
8.124 points

Name: points
controls the number of points chosen by Sollya in certain commands.

Library names:
void sollya_lib_set_points_and_print(sollya_obj_t)
void sollya_lib_set_points(sollya_obj_t)
sollya_obj_t sollya_lib_get_points()

Usage:
points = n : integer → void
points = n ! : integer → void
points : constant

Parameters:

• n represents the number of points

Description:

• points is a global variable. Its value represents the number of points used in numerical algorithms of Sollya (namely dirtyinfnorm, dirtyintegral, dirtyfindzeros, plot).

Example 1:

> f=x^2*sin(1/x);
> points=10;
The number of points has been set to 10.
> dirtyfindzeros(f, [0;1]);
[|0, 0.318309886183790671537767526745028724068919291480918|]
> points=100;
The number of points has been set to 100.
> dirtyfindzeros(f, [0;1]);
[|0, 2.4485375860291590118289809749617594159147637806224e-2, 3.97887357729738339422094084312385905086149114351147e-2, 4.54728408833986673625382181064326748669884702115589e-2, 5.3051647697928445256294587790838120678153215246819e-2, 6.3661977236758134330755605349005748413783858296183e-2, 7.95774715459476788444188168625718101729822870229e-2, 0.10610329639459689051258917558167624356306430493638, 0.15915494301985357688376372514362034459645740459, 0.318309886183790671537767526745028724068919291480918|]

See also: dirtyinfnorm §8.42, dirtyintegral §8.43, dirtyfindzeros §8.41, plot §8.122, diam §8.38, prec §8.129

8.125 postscript

Name: postscript
special value for commands plot and externalplot

Library names:
sollya_obj_t sollya_lib_postscript()
int sollya_lib_is_postscript(sollya_obj_t)

Description:

• postscript is a special value used in commands plot and externalplot to save the result of the command in a postscript file.

• As any value it can be affected to a variable and stored in lists.
Example 1:

```plaintext
> savemode=postscript;
> name="plotSinCos";
> plot(sin(x),0,cos(x),[-Pi,Pi],savemode, name);
```

### 8.126 postscriptfile

**Name:** postscriptfile  
Special value for commands `plot` and `externalplot`  

**Library names:**  
sollya_obj_t sollya_lib_postscriptfile()  
int sollya_lib_is_postscriptfile(sollya_obj_t)

**Description:**  
- *postscriptfile* is a special value used in commands `plot` and `externalplot` to save the result of the command in a data file and a postscript file.  
- As any value it can be affected to a variable and stored in lists.

**Example 1:**

```plaintext
> savemode=postscriptfile;
> name="plotSinCos";
> plot(sin(x),0,cos(x),[-Pi,Pi],savemode, name);
```

### 8.127 ^

**Name:** ^  
Power function

**Library names:**  
sollya_obj_t sollya_lib_pow(sollya_obj_t, sollya_obj_t)  
sollya_obj_t sollya_lib_build_function_pow(sollya_obj_t, sollya_obj_t)  
#define SOLLYA_POW(x,y) sollya_lib_build_function_pow((x), (y))

**Usage:**  

```
function1 ^ function2 : (function, function) \rightarrow function  
interval1 ^ interval2 : (range, range) \rightarrow range  
interval1 ^ constant : (range, constant) \rightarrow range  
interval1 ^ constant : (constant, range) \rightarrow range
```

**Parameters:**  
- *function1* and *function2* represent functions  
- *interval1* and *interval2* represent intervals (ranges)  
- *constant* represents a constant or constant expression

**Description:**  
- ^ represents the power (function) on reals. The expression *function1* ^ *function2* stands for the function composed of the power function and the two functions *function1* and *function2*, where *function1* is the base and *function2* the exponent. If *function2* is a constant integer, ^ is defined on negative values of *function1*. Otherwise ^ is defined as $e^{y \ln(x)}$.
• Note that whenever several \(^{\text{^\dagger}}\) are composed, the priority goes to the last \(^{\text{^\dagger}}\). This corresponds to the natural way of thinking when a tower of powers is written on a paper. Thus, \(2^{3^{5}}\) is read as \(2^{3^{5}}\) and is interpreted as \(2^{3^{5}}\).

• \(^{\text{^\dagger}}\) can be used for interval arithmetic on intervals (ranges). \(^{\text{^\dagger}}\) will evaluate to an interval that safely encompasses all images of the power function with arguments varying in the given intervals. If the intervals given contain points where the power function is not defined, infinities and NaNs will be produced in the output interval. Any combination of intervals with intervals or constants (resp. constant expressions) is supported. However, it is not possible to represent families of functions using an interval as one argument and a function (varying in the free variable) as the other one.

Example 1:

\[
\begin{align*}
> 5 ^ 2; \\
25
\end{align*}
\]

Example 2:

\[
\begin{align*}
> x ^ 2; \\
x^2
\end{align*}
\]

Example 3:

\[
\begin{align*}
> 3 ^ (-5); \\
4.1152263374485596707818930041152263374485596707818e-3
\end{align*}
\]

Example 4:

\[
\begin{align*}
> (-3) ^ (-2.5); \\
@NaN@
\end{align*}
\]

Example 5:

\[
\begin{align*}
> \text{diff(sin(x) ^ exp(x));} \\
\sin(x)^{\text{exp(x)} * ((\cos(x) * \text{exp(x)}) / \sin(x)) + \text{exp(x)} * \log(\sin(x)))}
\end{align*}
\]

Example 6:

\[
\begin{align*}
> 2^{3^{5}}; \\
1.413477651822707463666380005943348126619871175005e73 \\
> (2^{3})^{5}; \\
32768 \\
> 2^{(3^{5})}; \\
1.413477651822707463666380005943348126619871175005e73
\end{align*}
\]

Example 7:

\[
\begin{align*}
> [1;2] ^ [3;4]; \\
[1;1.6000000000000000000000000000000000000000000007e1] \\
> [1;2] ^ 17; \\
[1;131072] \\
> 13 ^ [-4;17]; \\
[3.501277966457757081334687160813696999404782745702e-5;8650415919381337933]
\end{align*}
\]

See also: + \(8.123\), − \(8.107\), * \(8.108\), / \(8.46\)

156
8.128 powers

Name: powers

special value for global state display

Library names:

sollya_obj_t sollya_lib_powers()
int sollya_lib_is_powers(sollya_obj_t)

Description:

- powers is a special value used for the global state display. If the global state display is equal to powers, all data will be output in dyadic notation with numbers displayed in a Maple and PARI/GP compatible format.

As any value it can be affected to a variable and stored in lists.

See also: decimal [8.34], dyadic [8.50], hexadecimal [8.78], binary [8.18], display [8.45]

8.129 prec

Name: prec

controls the precision used in numerical computations.

Library names:

void sollya_lib_set_prec_and_print(sollya_obj_t)
void sollya_lib_set_prec(sollya_obj_t)
sollya_obj_t sollya_lib_get_prec()

Description:

- prec is a global variable. Its value represents the precision of the floating-point format used in numerical computations.

- Many commands try to adapt their working precision in order to have approximately \( n \) correct bits in output, where \( n \) is the value of prec.

Example 1:

```
> display=binary!;
> prec=50;
The precision has been set to 50 bits.
> dirtyinfnorm(exp(x),[1;2]);
1.11011001110011001011101101110111111_2 * 2^2
> prec=100;
The precision has been set to 100 bits.
> dirtyinfnorm(exp(x),[1;2]);
1.11011001110011001011101101110111111_2 * 2^2
```

See also: evaluate [8.55], diam [8.38]

8.130 precision

Name: precision

returns the precision necessary to represent a number.

Library name:

sollya_obj_t sollya_lib_precision(sollya_obj_t)

Usage:

```
precision(x) : constant → integer
```
Parameters:

- $x$ is a dyadic number.

Description:

- **precision**($x$) is by definition $|x|$ if $x$ equals 0, NaN, or Inf.
- If $x$ is not zero, it can be uniquely written as $x = m \cdot 2^e$ where $m$ is an odd integer and $e$ is an integer. **precision**($x$) returns the number of bits necessary to write $m$ in binary (i.e. $\lceil \log_2(m) \rceil$).

Example 1:

```plaintext
> a=round(Pi,20,RN);
> precision(a);
19
> m=mantissa(a);
> ceil(log2(m));
19
```

See also: mantissa [8.102], exponent [8.60], round [8.155]

**8.131 .:**

Name: .:  
add an element at the beginning of a list.

Library name:

`sollya_obj_t sollya_lib_prepend(sollya_obj_t, sollya_obj_t)`

Usage:

```
x:L : (any type, list) → list
```

Parameters:

- $x$ is an object of any type.
- $L$ is a list (possibly empty).

Description:

- .: adds the element $x$ at the beginning of the list $L$.
- Note that since $x$ may be of any type, it can be in particular a list.

Example 1:

```plaintext
> 1.:[12,3,4];
[11, 2, 3, 4]
```

Example 2:

```plaintext
> [[1,2,3]]:.:[[4,5,6]];
[[[1, 2, 3]], 4, 5, 6]
```

Example 3:

```plaintext
> 1.:[[]];
[[1]]
```

See also: .: [8.7], @ [8.27]
8.132 print

Name: print
prints an expression

Usage:

\begin{align*}
\text{print}(expr_1, \ldots, expr_n) & : (\text{any type}, \ldots, \text{any type}) \rightarrow \text{void} \\
\text{print}(expr_1, \ldots, expr_n) > \text{filename} & : (\text{any type}, \ldots, \text{any type}, \text{string}) \rightarrow \text{void} \\
\text{print}(expr_1, \ldots, expr_n) >> \text{filename} & : (\text{any type}, \ldots, \text{any type}, \text{string}) \rightarrow \text{void}
\end{align*}

Parameters:

- \textit{expr} represents an expression
- \textit{filename} represents a character sequence indicating a file name

Description:

- \texttt{print}(expr_1, \ldots, expr_n) prints the expressions \textit{expr1} through \textit{exprn} separated by spaces and followed by a newline.

  If a second argument \textit{filename} is given after a single "">

  , the displaying is not output on the standard output of Sollya but if in the file \textit{filename} that get newly created or overwritten. If a double ">>>" is given, the output will be appended to the file \textit{filename}.

The global variables \texttt{display}, \texttt{midpointmode} and \texttt{fullparentheses} have some influence on the formatting of the output (see \texttt{display}, \texttt{midpointmode} and \texttt{fullparentheses}).

Remark that if one of the expressions \textit{expri} given in argument is of type \texttt{string}, the character sequence \textit{expri} evaluates to is displayed. However, if \textit{expri} is of type \texttt{list} and this list contains a variable of type \texttt{string}, the expression for the list is displayed, i.e. all character sequences get displayed surrounded by double quotes ("."). Nevertheless, escape sequences used upon defining character sequences are interpreted immediately.

Example 1:

```plaintext
> print(x + 2 + exp(sin(x)));  
x + 2 + exp(sin(x))  
> print("Hello","world");  
Hello world  
> print("Hello","you", 4 + 3, "other persons.");  
Hello you 7 other persons.
```

Example 2:

```plaintext
> print("Hello");  
Hello  
> print(["Hello"])  
["Hello"]  
> s = "Hello";  
> print(s,[s]);  
Hello ["Hello"]  
> t = "Hello\tyou";  
> print(t,[t]);  
Hello you ["Hello\tyou"]
```

Example 3:

```plaintext
> print(x + 2 + exp(sin(x))) > "foo.sol";  
> readfile("foo.sol");  
x + 2 + exp(sin(x))
```

159
Example 4:

```
> print(x + 2 + exp(sin(x))) >> "foo.sol";
```

Example 5:
> display = decimal;
Display mode is decimal numbers.
> a = evaluate(sin(pi * x), 0.25);
> b = evaluate(sin(pi * x), [0.25; 0.25 + 1b-50]);
> print(a);
0.7071067811865475244008443621048903283593768847
> display = binary;
Display mode is binary numbers.
> print(a);
1.011010100000101110101001110011100100100001000101101111101100010111110101111101101100010111101
010011_2 * 2^(-1)
> display = hexadecimal;
Display mode is hexadecimal numbers.
> print(a);
0xb.504f33f9de6484597d89b3754abe9f1d6f60ba88p-4
> display = dyadic;
Display mode is dyadic numbers.
> print(a);
3307006991101558613323983488220944360067107133265b-165
> display = powers;
Display mode is dyadic numbers in integer-power-of-2 notation.
> print(a);
3307006991101558613323983488220944360067107133265 * 2^-165
> display = decimal;
Display mode is decimal numbers.
> midpointmode = off;
Midpoint mode has been deactivated.
> print(b);

> display = decimal;
Display mode is decimal numbers.
> autosimplify = off;
Automatic pure tree simplification has been deactivated.
> fullparentheses = off;
Full parentheses mode has been deactivated.
> print(x + x * ((x + 1) + 1));
x + x * (x + 1 + 1)
> fullparentheses = on;
Full parentheses mode has been activated.
> print(x + x * ((x + 1) + 1));
x + (x * ((x + 1) + 1))

See also: write [8.192], printexpansion [8.134], printdouble [8.133], printsingle [8.135], printxml [8.136], readfile [8.146], autosimplify [8.15], display [8.45], midpointmode [8.105], fullparentheses [8.70], evaluate [8.55], rationalmode [8.144]
8.133 printdouble

Name: printdouble
prints a constant value as a hexadecimal double precision number

Library name:
void sollya_lib_printdouble(sollya_obj_t)

Usage:

printdouble(constant) : constant → void

Parameters:
• constant represents a constant

Description:
• Prints a constant value as a hexadecimal number on 16 hexadecimal digits. The hexadecimal number represents the integer equivalent to the 64 bit memory representation of the constant considered as a double precision number.

If the constant value does not hold on a double precision number, it is first rounded to the nearest double precision number before displayed. A warning is displayed in this case.

Example 1:

> printdouble(3);
0x4008000000000000

Example 2:

> prec=100!;
> verbosity = 1!;
> printdouble(exp(5));
Warning: the given expression is not a constant but an expression to evaluate. A faithful evaluation to 100 bits will be used.
Warning: rounding down occurred before printing a value as a double.
0x40628d389970338f

See also: printsingle [8.135], printexpansion [8.134], double [8.47]

8.134 printexpansion

Name: printexpansion
prints a polynomial in Horner form with its coefficients written as a expansions of double precision numbers

Library name:
void sollya_lib_printexpansion(sollya_obj_t)

Usage:

printexpansion(polynomial) : function → void

Parameters:
• polynomial represents the polynomial to be printed

Description:
• The command \texttt{printexpansion} prints the polynomial \textit{polynomial} in Horner form writing its coefficients as expansions of double precision numbers. The double precision numbers themselves are displayed in hexadecimal memory notation (see \texttt{printdouble}).

If some of the coefficients of the polynomial \textit{polynomial} are not floating-point constants but constant expressions, they are evaluated to floating-point constants using the global precision \texttt{prec}. If a rounding occurs in this evaluation, a warning is displayed.

If the exponent range of double precision is not sufficient to display all the mantissa bits of a coefficient, the coefficient is displayed rounded and a warning is displayed.

If the argument \textit{polynomial} does not a polynomial, nothing but a warning or a newline is displayed.

Constants can be displayed using \texttt{printexpansion} since they are polynomials of degree 0.

\textbf{Example 1}:
\begin{verbatim}
> printexpansion(roundcoefficients(taylor(exp(x),5,0),[[DD...]]));
0x3ff0000000000000 + x * (0x3ff0000000000000 + x * (0x3fe0000000000000 +
  x * ((0x3fc5555555555555 + 0x3c65555555555555) + x * ((0x3fa5555555555555 +
  0x3c455555555555555) + x * (0x3f81111111111111 + 0x3c01111111111111))))
\end{verbatim}

\textbf{Example 2}:
\begin{verbatim}
> printexpansion(remez(exp(x),5,[-1;1]));

\section{printsingle}

\textbf{Name}:
\texttt{printsingle} prints a constant value as a hexadecimal single precision number

\textbf{Library name}:
void sollya_lib_printsingle(sollya_obj_t)

\textbf{Usage}:
\begin{verbatim}
printsingle(constant) : constant \rightarrow \text{void}
\end{verbatim}
Parameters:

- *constant* represents a constant

Description:

- Prints a constant value as a hexadecimal number on 8 hexadecimal digits. The hexadecimal number represents the integer equivalent to the 32 bit memory representation of the constant considered as a single precision number.

  If the constant value does not hold on a single precision number, it is first rounded to the nearest single precision number before it is displayed. A warning is displayed in this case.

Example 1:

```plaintext
> printsingle(3);
0x40400000
```

Example 2:

```plaintext
> prec=100!;
> verbosity = 1!;
> printsingle(exp(5));
Warning: the given expression is not a constant but an expression to evaluate. A faithful evaluation to 100 bits will be used.
Warning: rounding down occurred before printing a value as a single.
0x431469c5
```

See also: *printdouble* [8.133], *single* [8.166]

8.136 printxml

Name: *printxml*

prints an expression as an MathML-Content-Tree

Library names:

```plaintext
void sollya_lib_printxml(sollya_obj_t)
void sollya_lib_printxml_newfile(sollya_obj_t, sollya_obj_t)
void sollya_lib_printxml_appendfile(sollya_obj_t, sollya_obj_t)
```

Usage:

```plaintext
printxml(expr) : function → void
printxml(expr) > filename : (function, string) → void
printxml(expr) >> filename : (function, string) → void
```

Parameters:

- *expr* represents a functional expression
- *filename* represents a character sequence indicating a file name

Description:

- *printxml(expr)* prints the functional expression *expr* as a tree of MathML Content Definition Markups. This XML tree can be re-read in external tools or by usage of the *readxml* command.

  If a second argument *filename* is given after a single >, the MathML tree is not output on the standard output of *Sollya* but if in the file *filename* that get newly created or overwritten. If a double >> is given, the output will be appended to the file *filename*.

Example 1:
Example 2:

```bash
> printxml(x + 2 + exp(sin(x))) > "foo.xml";
```

Example 3:

```bash
> printxml(x + 2 + exp(sin(x))) >> "foo.xml";
```

See also: readxml \[8.147\], print \[8.132\], write \[8.192\]

8.137 proc

Name: proc
defines a Sollya procedure

Usage:
\textbf{proc}(\textit{formal parameter} 1, \textit{formal parameter} 2, \ldots, \textit{formal parameter} \textit{n}) \{ \text{ procedure body } \} : \text{ void } \rightarrow \text{ procedure}

\textbf{proc}(\textit{formal parameter} 1, \textit{formal parameter} 2, \ldots, \textit{formal parameter} \textit{n}) \{ \text{ procedure body return expression; } \} : \text{ void } \rightarrow \text{ procedure}

\textbf{proc}(\textit{formal list parameter} = \ldots) \{ \text{ procedure body } \} : \text{ void } \rightarrow \text{ procedure}

\textbf{proc}(\textit{formal list parameter} = \ldots) \{ \text{ procedure body return expression; } \} : \text{ void } \rightarrow \text{ procedure}

Parameters:

- \textit{formal parameter} 1, \textit{formal parameter} 2 through \textit{formal parameter} \textit{n} represent identifiers used as formal parameters

- \textit{formal list parameter} represents an identifier used as a formal parameter for the list of an arbitrary number of parameters

- \textit{procedure body} represents the imperative statements in the body of the procedure

- \textit{expression} represents the expression \textbf{proc} shall evaluate to

Description:

- The \textbf{proc} keyword allows for defining procedures in the \texttt{Sollya} language. These procedures are \texttt{Sollya} objects that can be applied to actual parameters after definition. Upon such an application, the \texttt{Sollya} interpreter applies the actual parameters to the formal parameters \textit{formal parameter} 1 through \textit{formal parameter} \textit{n} (resp. builds up the list of arguments and applies it to the list \textit{formal list parameter}) and executes the \textit{procedure body}. The procedure applied to actual parameters evaluates then to the expression \texttt{expression} in the \texttt{return} statement after the \textit{procedure body} or to \texttt{void}, if no return statement is given (i.e. a \texttt{return void} statement is implicitly given).

- \texttt{Sollya} procedures defined by \textbf{proc} have no name. They can be bound to an identifier by assigning the procedure object a \textbf{proc} expression produces to an identifier. However, it is possible to use procedures without giving them any name. For instance, \texttt{Sollya} procedures, i.e. procedure objects, can be elements of lists. They can even be given as an argument to other internal \texttt{Sollya} procedures. See also \texttt{procedure} on this subject.

- Upon definition of a \texttt{Sollya} procedure using \textbf{proc}, no type check is performed. More precisely, the statements in \textit{procedure body} are merely parsed but not interpreted upon procedure definition with \textbf{proc}. Type checks are performed once the procedure is applied to actual parameters or to \texttt{void}. At this time, if the procedure was defined using several different formal parameters \textit{formal parameter} 1 through \textit{formal parameter} \textit{n}, it is checked whether the number of actual parameters corresponds to the number of formal parameters. If the procedure was defined using the syntax for a procedure with an arbitrary number of parameters by giving a \texttt{formal list parameter}, the number of actual arguments is not checked but only a list \texttt{formal list parameter} of appropriate length is built up. Type checks are further performed upon execution of each statement in \textit{procedure body} and upon evaluation of the expression \texttt{expression} to be returned.

- Procedures defined by \textbf{proc} containing a \texttt{quit} or \texttt{restart} command cannot be executed (i.e. applied). Upon application of a procedure, the \texttt{Sollya} interpreter checks beforehand for such a statement. If one is found, the application of the procedure to its arguments evaluates to \texttt{error}. A warning is displayed. Remark that in contrast to other type or semantic correctness checks, this check is really performed before interpreting any other statement in the body of the procedure.

- Through the \texttt{var} keyword it is possible to declare local variables and thus to have full support of recursive procedures. This means a procedure defined using \textbf{proc} may contain in its \textit{procedure body} an application of itself to some actual parameters: it suffices to assign the procedure (object) to an identifier with an appropriate name.

- \texttt{Sollya} procedures defined using \textbf{proc} may return other procedures. Further \textit{procedure body} may contain assignments of locally defined procedure objects to identifiers. See \texttt{var} for the particular behaviour of local and global variables.
The expression expression returned by a procedure is evaluated with regard to Sollya commands, procedures and external procedures. Simplification may be performed. However, an application of a procedure defined by proc to actual parameters evaluates to the expression expression that may contain the free global variable or that may be composed.

Example 1:

```plaintext
> succ = proc(n) { return n + 1; };  
> succ(5);  
6  
> 3 + succ(0);  
4  
> succ;  
proc(n)  
{  
  nop;  
  return (n) + (1);  
}
```

Example 2:

```plaintext
> add = proc(m,n) { var res; res := m + n; return res; };  
> add(5,6);  
11  
> add;  
proc(m, n)  
{  
  var res;  
  res := (m) + (n);  
  return res;  
}  
> verbosity = 1!;  
> add(3);  
Warning: at least one of the given expressions or a subexpression is not correctly typed  
or its evaluation has failed because of some error on a side-effect.  
error  
> add(true,false);  
Warning: at least one of the given expressions or a subexpression is not correctly typed  
or its evaluation has failed because of some error on a side-effect.  
Warning: the given expression or command could not be handled.  
error
```

Example 3:

```plaintext
> succ = proc(n) { return n + 1; };  
> succ(5);  
6  
> succ(x);  
1 + x
```

Example 4:
Example 5:

```plaintext
> hey = proc() { print("Hello world."); }; 
> hey(); 
Hello world. 
> print(hey()); 
Hello world. 
void 
> hey; 
proc() 
{ 
print("Hello world."); 
return void; 
}
```

Example 6:

```plaintext
> fac = proc(n) { var res; if (n == 0) then res := 1 else res := n * fac(n - 1); 
return res; }; 
> fac(5); 
120 
> fac(11); 
39916800 
> fac; 
proc(n) 
{ 
var res; 
if (n) == (0) then 
res := 1 
else 
res := (n) * (fac((n) - (1))); 
return res; 
}
```

Example 7:

```plaintext
> myprocs = [| proc(m,n) { return m + n; }, proc(m,n) { return m - n; } |]; 
> (myprocs[0])(5,6); 
11 
> (myprocs[1])(5,6); 
-1 
> succ = proc(n) { return n + 1; }; 
> pred = proc(n) { return n - 1; }; 
> applier = proc(p,n) { return p(n); }; 
> applier(succ,5); 
6 
> applier(pred,5); 
4
```
Example 8:

```nsl
> verbosity = 1!
> myquit = proc(n) { print(n); quit; }
> myquit
proc(n)
{
    print(n);
    quit;
    return void;
}
> myquit(5);
Warning: a quit or restart command may not be part of a procedure body.
The procedure will not be executed.
Warning: an error occurred while executing a procedure.
Warning: the given expression or command could not be handled.
error
```

Example 9:

```nsl
Example 9:

> printsucc = proc(n) { var succ; succ = proc(n) { return n + 1; }; print("Successor of",n,"is",succ(n)); }
> printsucc(5);
Successor of 5 is 6
```

Example 10:

```nsl
Example 10:

> makeadd = proc(n) { var add; print("n =",n); add = proc(m,n) { return n + m; } ; return add; }
> makeadd(4);
n = 4
proc(m, n)
{
    nop;
    return (n) + (m);
}
> (makeadd(4))(5,6);
n = 4
11
```
```plaintext
> sumall = proc(L = ...) { var acc, i; acc = 0; for i in L do acc = acc + i; return acc; }
> sumall;
proc(L = ...) {
  var acc, i;
  acc = 0;
  for i in L do
    acc = (acc) + (i);
  return acc;
}
> sumall();
0
> sumall(2);
2
> sumall(2,5);
7
> sumall(2,5,7,9,16);
39
> sumall @ [1,...,10];
55
```

See also: return (8.152), externalproc (8.62), void (8.190), quit (8.141), restart (8.151), var (8.188), @ (8.27), bind (8.19), error (8.54)

8.138  procedure

Name:  procedure

  defines and assigns a Sollya procedure

Usage:

procedure  identifier(formal parameter1, formal parameter2,..., formal parameter n) { procedure body }
            : void → void
procedure  identifier(formal parameter1, formal parameter2,..., formal parameter n) { procedure body
            return expression; } : void → void
procedure  identifier(formal list parameter = ...) { procedure body } : void → void
procedure  identifier(formal list parameter = ...) { procedure body return expression; } : void → void

Parameters:

- identifier  represents the name of the procedure to be defined and assigned
- formal parameter1, formal parameter2 through formal parameter n represent identifiers used as formal parameters
- formal list parameter represents an identifier used as a formal parameter for the list of an arbitrary number of parameters
- procedure body represents the imperative statements in the body of the procedure
- expression  represents the expression procedure shall evaluate to

Description:

- The procedure keyword allows for defining and assigning procedures in the Sollya language. It is an abbreviation to a procedure definition using proc with the same formal parameters, procedure body and return-expression followed by an assignment of the procedure (object) to the identifier identifier. In particular, all rules concerning local variables declared using the var keyword apply for procedure.
Example 1:

```plaintext
> procedure succ(n) { return n + 1; };
> succ(5);
6
> 3 + succ(0);
4
> succ;
proc(n)
{
  nop;
  return (n) + (1);
}
```

Example 2:

```plaintext
> procedure myprint(L = ...) { var i; for i in L do i; };
> myprint("Lyon","Nancy","Beaverton","Coye-la-Forêt","Amberg","Nizhny Novgorod","Cluj-Napoca");
Lyon
Nancy
Beaverton
Coye-la-Forêt
Amberg
Nizhny Novgorod
Cluj-Napoca
```

See also: proc (8.137), var (8.188), bind (8.19)

### 8.139 QD

**Name:** QD

short form for quad

See also: quad (8.140)

### 8.140 quad

**Names:** quad, QD

rounding to the nearest IEEE 754 quad (binary128).

**Library names:**

- `sollya_obj_t sollya_lib_quad(sollya_obj_t)`
- `sollya_obj_t sollya_lib_quad_obj()`
- `int sollya_lib_is_quad_obj(sollya_obj_t)`
- `sollya_obj_t sollya_lib_build_function_quad(sollya_obj_t)`
- `#define SOLLYA_QD(x) sollya_lib_build_function_quad(x)`

**Description:**

- **quad** is both a function and a constant.
- As a function, it rounds its argument to the nearest IEEE 754 quad precision (i.e. IEEE754-2008 binary128) number. Subnormal numbers are supported as well as standard numbers: it is the real rounding described in the standard.
- As a constant, it symbolizes the quad precision format. It is used in contexts when a precision format is necessary, e.g. in the commands `round` and `roundcoefficients`. It is not supported for `implementpoly`. See the corresponding help pages for examples.
Example 1:

```latex
\begin{verbatim}
> display=binary!;
> QD(0.1);
1.100110011001100110011001100110011001100110011001100110011001100110011001100110
01100110011001100110011001100110011001101_2 * 2^(-4)
> QD(4.17);
1.000010101110000101000111101011100001010001111010111000010100011110101110000101
0001110110111000010100011110101110111_2 * 2^2
> QD(1.011_2 * 2^(-16493));
1.1_2 * 2^(-16493)
\end{verbatim}
```

See also: halfprecision (8.76), single (8.166), double (8.47), doubleextended (8.49), doubledouble (8.48), tripledouble (8.185), roundcoefficients (8.156), implementpoly (8.84), fpminimax (8.69), round (8.155), printsingle (8.135)

### 8.141 quit

**Name:** quit

quilts Sollya

**Usage:**

```plaintext
quit : void → void
```

**Description:**

- The command `quit`, when executed, stops the execution of a Sollya script and leaves the Sollya interpreter unless the `quit` command is executed in a Sollya script read into a main Sollya script by `execute` or `#include`.

Upon exiting the Sollya interpreter, all state is thrown away, all memory is deallocated, all bound libraries are unbound and the temporary files produced by `plot` and `externalplot` are deleted.

If the `quit` command does not lead to a halt of the Sollya interpreter, a warning is displayed.

**Example 1:**

```plaintext
> quit;
```

See also: restart (8.151), execute (8.56), plot (8.122), externalplot (8.61), return (8.152)

### 8.142 range

**Name:** range

keyword representing a range type

**Usage:**

```plaintext
range : type type
```

**Description:**

- `range` represents the range type for declarations of external procedures by means of `externalproc`.

Remark that in contrast to other indicators, type indicators like `range` cannot be handled outside the `externalproc` context. In particular, they cannot be assigned to variables.

See also: externalproc (8.62), boolean (8.20), constant (8.28), function (8.71), integer (8.88), list of (8.96), string (8.170), object (8.115)
8.143 rationalapprox

Name: **rationalapprox**

returns a fraction close to a given number.

Library name:

```
sollya_obj_t sollya_lib_rationalapprox(sollya_obj_t, sollya_obj_t)
```

Usage:

```
rationalapprox(x, n) : (constant, integer) → function
```

Parameters:

- `x` is a number to approximate.
- `n` is an integer (representing a format).

Description:

- **rationalapprox**(x, n) returns a constant function of the form a/b where a and b are integers. The value a/b is an approximation of x. The quality of this approximation is determined by the parameter n that indicates the number of correct bits that a/b should have.
- The command is not safe in the sense that it is not ensured that the error between a/b and x is less than 2^{-n}.
- The following algorithm is used: x is first rounded downwards and upwards to a format of n bits, thus obtaining an interval [x_l, x_u]. This interval is then developed into a continued fraction as far as the representation is the same for every elements of [x_l, x_u]. The corresponding fraction is returned.
- Since rational numbers are not a primitive object of Sollya, the fraction is returned as a constant function. This can be quite amazing, because Sollya immediately simplifies a constant function by evaluating it when the constant has to be displayed. To avoid this, you can use print (that displays the expression representing the constant and not the constant itself) or the commands numerator and denominator.

Example 1:

```
> pi10  = rationalapprox(Pi,10);  
> pi50  = rationalapprox(Pi,50);  
> pi100 = rationalapprox(Pi,100); 
> print( pi10, " : ", dirtysimplify(floor(-log2(abs(pi10-Pi)/Pi))), "bits." );
3.140625 : 11 bits.
> print( pi50, " : ", dirtysimplify(floor(-log2(abs(pi50-Pi)/Pi))), "bits." );
85563208 / 27235615 : 51 bits.
> print( pi100, " : ", dirtysimplify(floor(-log2(abs(pi100-Pi)/Pi))), "bits." );
4422001152019829 / 1407566683404023 : 100 bits.
```

Example 2:

```
> a=0.1;  
> b=rationalapprox(a,4);  
> numerator(b); denominator(b); 
1
10
> print(dirtysimplify(floor(-log2(abs((b-a)/a)))), "bits.");
166 bits.
```

See also: [print](8.132), [numerator](8.114), [denominator](8.37), [rationalmode](8.144)
8.144 rationalmode

Name: rationalmode
  global variable controlling if rational arithmetic is used or not.

Library names:
  void sollya_lib_set_rationalmode_and_print(sollya_obj_t)
  void sollya_lib_set_rationalmode(sollya_obj_t)
  sollya_obj_t sollya_lib_get_rationalmode()

Usage:
  rationalmode = activation value : on|off → void
  rationalmode = activation value ! : on|off → void
  rationalmode : on|off

Parameters:
  • activation value controls if rational arithmetic should be used or not

Description:
  • rationalmode is a global variable. When its value is off, which is the default, Sollya will
    not use rational arithmetic to simplify expressions. All computations, including the evaluation
    of constant expressions given on the Sollya prompt, will be performed using floating-point and
    interval arithmetic. Constant expressions will be approximated by floating-point numbers, which
    are in most cases faithful roundings of the expressions, when shown at the prompt.

  • When the value of the global variable rationalmode is on, Sollya will use rational arithmetic
    when simplifying expressions. Constant expressions, given at the Sollya prompt, will be simplified
    to rational numbers and displayed as such when they are in the set of the rational numbers. Other-
    wise, floating-point and interval arithmetic will be used to compute a floating-point approximation,
    which is in most cases a faithful rounding of the constant expression.

Example 1:

> rationalmode=off!;
> 19/17 + 3/94;
1.1495619524405506883604505632040050062578222778473
> rationalmode=on!;
> 19/17 + 3/94;
1837 / 1598

Example 2:

> rationalmode=off!;
> exp(19/17 + 3/94);
3.15680977395514136754709208944824276340328162814418
> rationalmode=on!;
> exp(19/17 + 3/94);
3.15680977395514136754709208944824276340328162814418

See also: on [8.117], off [8.116], numerator [8.114], denominator [8.37], simplify [8.164], rationalapprox [8.143], autosimplify [8.15]

8.145 RD

Name: RD
  constant representing rounding-downwards mode.

Library names:
sollya_obj_t sollya_lib_round_down()
int sollya_lib_is_round_down(sollya_obj_t)

Description:

- **RD** is used in command *round* to specify that the value $x$ must be rounded to the greatest floating-point number $y$ such that $y \leq x$.

Example 1:

```
> display=binary!;
> round(Pi,20,RD);
1.1001001000011111101_2 * 2^(1)
```

See also: RZ [8.160], RU [8.159], RN [8.154], round [8.155], floor [8.68]

### 8.146 readfile

**Name:** readfile

reads the content of a file into a string variable

**Usage:**

```
readfile(filename) : string → string
```

**Parameters:**

- *filename* represents a character sequence indicating a file name

**Description:**

- **readfile** opens the file indicated by *filename*, reads it and puts its contents in a character sequence of type string that is returned.
  
  If the file indicated by *filename* cannot be opened for reading, a warning is displayed and **readfile** evaluates to an **error** variable of type **error**.

Example 1:

```
> print("Hello world") > "myfile.txt";
> t = readfile("myfile.txt");
> t;
Hello world
```

Example 2:

```
> verbosity=1!;
> readfile("afile.txt");
Warning: the file "afile.txt" could not be opened for reading.
Warning: at least one of the given expressions or a subexpression is not correctly typed

8.147 readxml

Name: *readxml*

reads an expression written as a MathML-Content-Tree in a file

Library name:

\[ \texttt{sollya\_obj\_t sollya\_lib\_readxml(sollya\_obj\_t)} \]

Usage:

\[
\texttt{readxml(filename) : string} \rightarrow \text{function | error}
\]

Parameters:

- *filename* represents a character sequence indicating a file name

Description:

- \texttt{readxml(filename)} reads the first occurrence of a lambda application with one bounded variable on applications of the supported basic functions in file *filename* and returns it as a Sollya functional expression.

If the file *filename* does not contain a valid MathML-Content tree, \texttt{readxml} tries to find an ”annotation encoding” markup of type ”sollya/text”. If this annotation contains a character sequence that can be parsed by \texttt{parse}, \texttt{readxml} returns that expression. Otherwise \texttt{readxml} displays a warning and returns an error variable of type \texttt{error}.

Example 1:

\[
> \texttt{readxml("readxml\_example.xml");}
2 + _x_ + \exp(\sin(_x_))
\]

See also: printxml (8.136), readfile (8.146), parse (8.119), error (8.54)

8.148 relative

Name: *relative*

indicates a relative error for externalplot, fpminimax or supnorm

Library names:

\[ \texttt{sollya\_obj\_t sollya\_lib\_relative()} \]
\[ \text{int sollya\_lib\_is\_relative(sollya\_obj\_t)} \]

Usage:

\[
\texttt{relative : absolute|relative}
\]

Description:

- The use of \texttt{relative} in the command \texttt{externalplot} indicates that during plotting in \texttt{externalplot} a relative error is to be considered.

See \texttt{externalplot} for details.

- Used with \texttt{fpminimax}, \texttt{relative} indicates that \texttt{fpminimax} must try to minimize the relative error.

See \texttt{fpminimax} for details.

- When given in argument to \texttt{supnorm}, \texttt{relative} indicates that a relative error is to be considered for supremum norm computation.

See \texttt{supnorm} for details.

Example 1:
bashexecute("gcc -fPIC -c externalplotexample.c");
bashexecute("gcc -shared -o externalplotexample externalplotexample.o -lgmp -lm

 externalplot("./externalplotexample",absolute,exp(x),[-1/2;1/2],12,perturb);

See also: externalplot [8.61], fpminimax [8.69], absolute [8.2], bashexecute [8.17], supnorm [8.174]

8.149  remez

Name: remez
computes the minimax of a function on an interval.

Library names:
  sollya_obj_t sollya_lib_remez(sollya_obj_t, sollya_obj_t, sollya_obj_t, ...)
  sollya_obj_t sollya_lib_v_remez(sollya_obj_t, sollya_obj_t, sollya_obj_t,
                                va_list)

Usage:
remez(f, n, range, w, quality, bounds) : (function, integer, range, function, constant, range) → function
remez(f, L, range, w, quality, bounds) : (function, list, range, function, constant, range) → function

Parameters:
• f is the function to be approximated
• n is the degree of the polynomial that must approximate f
• L is a list of integers or a list of functions and indicates the basis for the approximation of f
• range is the interval where the function must be approximated
• w (optional) is a weight function. Default is 1.
• quality (optional) is a parameter that controls the quality of the returned polynomial p, with respect
to the exact minimax p*. Default is 1e-5.
• bounds (optional) is a parameter that allows the user to make the algorithm stop earlier, whenever
given accuracy is reached or a given accuracy is proved unreachable. Default is [0, +∞].

Description:
• remez computes an approximation of the function f with respect to the weight function w on the
  interval range. More precisely, it searches p such that \( \|pw - f\|_\infty \) is (almost) minimal among all p
  of a certain form. The norm is the infinity norm, e.g. \( \|g\|_\infty = \max\{|g(x)|, x \in range\} \).
• If \( w = 1 \) (the default case), it consists in searching the best polynomial approximation of f
  with respect to the absolute error. If \( f = 1 \) and w is of the form 1/g, it consists in searching the best
  polynomial approximation of g with respect to the relative error.
• If n is given, p is searched among the polynomials with degree not greater than n. If L is given
  and is a list of integers, p is searched as a linear combination of monomials \( X^k \) where \( k \) belongs to
  L. In the case when L is a list of integers, it may contain ellipses but cannot be end-elliptic. If L is
  given and is a list of functions \( g_k \), p is searched as a linear combination of the \( g_k \). In that case L
  cannot contain ellipses. It is the user responsibility to check that the \( g_k \) are linearly independent
  over the interval range. Moreover, the functions \( w \cdot g_k \) must be at least twice differentiable over
  range. If these conditions are not fulfilled, the algorithm might fail or even silently return a result
  as if it successfully found the minimax, though the returned p is not optimal.
The polynomial is obtained by a convergent iteration called Remez’ algorithm (and an extension of this algorithm, due to Stiefel). The algorithm computes a sequence $p_1, \ldots, p_k, \ldots$ such that $e_k = \|p_k w - f\|_\infty$ converges towards the optimal value $e$. The algorithm is stopped when the relative error between $e_k$ and $e$ is less than $quality$.

The optional argument $bounds$ is an interval $[\varepsilon_\ell, \varepsilon_u]$ with the following behavior:

- if, during the algorithm, we manage to prove that $\varepsilon_u$ is unreachable, we stop the algorithm returning the last computed polynomial.
- if, during the algorithm, we obtain a polynomial with an error smaller than $\varepsilon_\ell$, we stop the algorithm returning that polynomial.
- otherwise we loop until we find an optimal polynomial with the required quality, as usual.

Examples of use:

- $[0, +\infty]$ (compute the optimal polynomial with the required quality)
- $[\varepsilon_u]$ (stops as soon as a polynomial achieving $\varepsilon_u$ is obtained or as soon as such a polynomial is proved not to exist).
- $[0, \varepsilon_u]$ (finds the optimal polynomial, but provided that its error is smaller than $\varepsilon_u$).
- $[\varepsilon_\ell, +\infty]$ (stops as soon as a polynomial achieving $\varepsilon_\ell$ is obtained. If such a polynomial does not exist, returns the optimal polynomial).

Example 1:

```matlab
> p = remez(exp(x),5,[0;1]);
> degree(p);
5
> dirtyinfnorm(p-exp(x),[0;1]);
1.129569815109614870717193829266077607226345893629e-6
```

Example 2:

```matlab
> p = remez(1,[0,2,4,6,8],[0,Pi/4],1/cos(x));
> canonical=on!;
> p;
0.99999999943373218095969035253887130348096061124 + -0.4999999571556857768772053063721544670949467222587 * x^-2 + 4.166663233473633009941059480570275870113220089059e-2 * x^-4 + -1.3886529147145693651355523880319714051047635695061e-3 * x^-6 + 2.4372679177224179934800328511009205218114284220126e-5 * x^-8
```

Example 3:

```matlab
> p1 = remez(exp(x),5,[0;1],default,1e-5);
> p2 = remez(exp(x),5,[0;1],default,1e-10);
> p3 = remez(exp(x),5,[0;1],default,1e-15);
> dirtyinfnorm(p1-exp(x),[0;1]);
1.129569815109614870717193829266077607226345893629e-6
> dirtyinfnorm(p2-exp(x),[0;1]);

### 8.150 rename

**Name:** rename

rename the free variable.

**Library name:**

```c
void sollya_lib_name_free_variable(const char *)
```

**Usage:**

```plaintext
rename(ident1, ident2) : void
```

**Parameters:**

- `ident1` is the current name of the free variable.
- `ident2` is a fresh name.

**Description:**

- `rename` permits a change of the name of the free variable. Sollya can handle only one free variable at a time. The first time in a session that an unbound name is used in a context where it can be interpreted as a free variable, the name is used to represent the free variable of Sollya. In the following, this name can be changed using `rename`.

179
• Be careful: if $\text{ident2}$ has been set before, its value will be lost. Use the command \texttt{isbound} to know if $\text{ident2}$ is already used or not.

• If $\text{ident1}$ is not the current name of the free variable, an error occurs.

• If \texttt{rename} is used at a time when the name of the free variable has not been defined, $\text{ident1}$ is just ignored and the name of the free variable is set to $\text{ident2}$.

• It is always possible to use the special keyword \_\_x\_ to denote the free variable. Hence $\text{ident1}$ can be \_\_x\_.

Example 1:

```plaintext
> f=sin(x);
> f;
sin(x)
> rename(x,y);
> f;
sin(y)
```

Example 2:

```plaintext
> a=1;
> f=sin(x);
> rename(x,a);
> a;
a
> f;
sin(a)
```

Example 3:

```plaintext
> verbosity=1!;
> f=sin(x);
> rename(y, z);
Warning: the current free variable is named "x" and not "y". Can only rename the
free variable.
The last command will have no effect.
> rename(_x_, z);
Information: the free variable has been renamed from "x" to "z".
```

Example 4:

```plaintext
> verbosity=1!;
> rename(x,y);
 Information: the free variable has been named "y".
> isbound(x);
false
> isbound(y);
true
```

See also: \texttt{isbound} \[8.90]\n
\textbf{8.151 restart}

\textbf{Name:} restart

brings Sollya back to its initial state

\textbf{Usage:}
restart : void → void

Description:

- The command restart brings Sollya back to its initial state. All current state is abandoned, all libraries unbound and all memory freed.

The restart command has no effect when executed inside a Sollya script read into a main Sollya script using execute. It is executed in a Sollya script included by a #include macro.

Using the restart command in nested elements of imperative programming like for or while loops is possible. Since in most cases abandoning the current state of Sollya means altering a loop invariant, warnings for the impossibility of continuing a loop may follow unless the state is rebuilt.

Example 1:

```plaintext
> print(exp(x));
exp(x)
> a = 3;
> restart;
The tool has been restarted.
> print(x);
x
> a;
Warning: the identifier "a" is neither assigned to, nor bound to a library function nor external procedure, nor equal to the current free variable.
Will interpret "a" as "x".
x
```

Example 2:

```plaintext
> print(exp(x));
exp(x)
> for i from 1 to 10 do {
    print(i);
    if (i == 5) then restart;
}
1
2
3
4
5
The tool has been restarted.
Warning: the tool has been restarted inside a for loop.
The for loop will no longer be executed.
```

Example 3:

```plaintext
> print(exp(x));
exp(x)
> for i from 1 to 10 do {
    print(i);
    if (i == 5) then restart;
}
1
2
3
4
5
```

181
> print(exp(x));
exp(x)
> a = 3;
> for i from 1 to 10 do {
   print(i);
   if (i == 5) then {
      restart;
      i = 7;
   }
};
1
2
3
4
5
The tool has been restarted.
8
9
10
> print(x);
x
> a;
Warning: the identifier "a" is neither assigned to, nor bound to a library function nor external procedure, nor equal to the current free variable.
Will interpret "a" as "x".
x
See also: quit [8.141], execute [8.56]

8.152 return

Name: return
indicates an expression to be returned in a procedure
Usage:

   return expression : void

Parameters:

   • expression represents the expression to be returned

Description:

   • The keyword return allows for returning the (evaluated) expression expression at the end of a begin-end-block (-block) used as a Sollya procedure body. See proc for further details concerning Sollya procedure definitions.

   Statements for returning expressions using return are only possible at the end of a begin-end-block used as a Sollya procedure body. Only one return statement can be given per begin-end-block.

   • If at the end of a procedure definition using proc no return statement is given, a return void statement is implicitly added. Procedures, i.e. procedure objects, when printed out in Sollya defined with an implicit return void statement are displayed with this statement explicitly given.

Example 1:
> succ = proc(n) { var res; res := n + 1; return res; }
> succ(5);
> 6
> succ
> proc(n)
> {
>  var res;
>  res := (n) + (1);
>  return res;
> }

Example 2:

> hey = proc(s) { print("Hello",s); }
> hey("world");
Hello world
> hey
> proc(s)
> {
>  print("Hello", s);
>  return void;
> }

See also: proc (8.137), void (8.190)

8.153 revert

Name: revert
reverts a list.

Library name:
sollya_obj_t sollya_lib_revert(sollya_obj_t)

Usage:

revert(L) : list → list

Parameters:

• L is a list.

Description:

• revert(L) returns the same list, but with its elements in reverse order.

• If L is an end-elliptic list, revert will fail with an error.

Example 1:

> revert([1 1]);
[1 1]

Example 2:

> revert([12,3,5,2,1,4]);
[4, 1, 2, 5, 3, 2]
8.154 RN

Name: RN
constant representing rounding-to-nearest mode.

Library names:
- sollya_obj_t sollya_lib_round_to_nearest()
- int sollya_lib_is_round_to_nearest(sollya_obj_t)

Description:
- RN is used in command round to specify that the value must be rounded to the nearest representable floating-point number.

Example 1:
```plaintext
> display=binary!;
> round(Pi,20,RN);
1.100100100001111111_2 * 2^1
```

See also: RD [8.145], RU [8.159], RZ [8.160], round [8.155], nearestint [8.109]

8.155 round

Name: round
rounds a number to a floating-point format.

Library name:
- sollya_obj_t sollya_lib_round(sollya_obj_t, sollya_obj_t, sollya_obj_t)

Usage:
- round(x,n,mode) : (constant, integer, RN|RZ|RU|RD) → constant
- round(x,format,mode) : (constant, HP|halfprecision|SG|single|D|double|DE|doubleextended|DD|doubledouble|QD|quad|TD|tripledouble, RN|RZ|RU|RD) → constant

Parameters:
- x is a constant to be rounded.
- n is the precision of the target format.
- format is the name of a supported floating-point format.
- mode is the desired rounding mode.

Description:
- If used with an integer parameter n, round(x,n,mode) rounds x to a floating-point number with precision n, according to rounding-mode mode.
- If used with a format parameter format, round(x,format,mode) rounds x to a floating-point number in the floating-point format format, according to rounding-mode mode.
- Subnormal numbers are handled for the case when format is one of halfprecision, single, double, doubleextended, doubledouble, quad or tripledouble. Otherwise, when format is an integer, round does not take any exponent range into consideration, i.e. typically uses the full exponent range of the underlying MPFR library.
- It is worth mentioning that the result of round does not depend on the current global precision of Sollya, unless a warning is displayed. As a matter of fact, round rounds the given constant or constant expression x applying all rules of IEEE 754 correct rounding, unless a warning is displayed. The result of round is hence the floating-point value of the given precision n or format format that is nearest to x (resp. just below or just above, depending on mode), computed as if infinite precision were used for evaluating the constant x, unless a warning is displayed.
Example 1:

```latex
\begin{verbatim}
> display=binary!;
> round(Pi,20,RN);
1.100100100001111111_2 * 2^(1)
\end{verbatim}
```

Example 2:

```latex
\begin{verbatim}
> printdouble(round(exp(17),53,RU));
0x417709348c0ea4f9
> printdouble(D(exp(17)));
0x417709348c0ea4f9
\end{verbatim}
```

Example 3:

```latex
\begin{verbatim}
> display=binary!;
> a=2^(-1100);
> round(a,53,RN);
1_2 * 2^(-1100)
> round(a,D,RN);
0
> double(a);
0
\end{verbatim}
```

See also: RN \(^{[8.154]}\), RD \(^{[8.145]}\), RU \(^{[8.159]}\), RZ \(^{[8.160]}\), halfprecision \(^{[8.76]}\), single \(^{[8.166]}\),
double \(^{[8.47]}\), doubleextended \(^{[8.49]}\), doubledouble \(^{[8.48]}\), quad \(^{[8.140]}\), tripledouble \(^{[8.185]}\),
roundcoefficients \(^{[8.156]}\), roundcorrectly \(^{[8.157]}\), printdouble \(^{[8.133]}\), printsingle \(^{[8.135]}\), ceil \(^{[8.22]}\),
floor \(^{[8.68]}\), nearestint \(^{[8.109]}\)

8.156 roundcoefficients

Name: roundcoefficients

rounds the coefficients of a polynomial to classical formats.

Library name:

\texttt{sollya\_obj\_t sollya\_lib\_roundcoefficients(sollya\_obj\_t, sollya\_obj\_t)}

Usage:

\[
\text{roundcoefficients}(p,L) : (\text{function, list}) \rightarrow \text{function}
\]

Parameters:

- \(p\) is a function. Usually a polynomial.
- \(L\) is a list of formats.

Description:

- If \(p\) is a polynomial and \(L\) a list of floating-point formats, \texttt{roundcoefficients}(p,L) rounds each
  coefficient of \(p\) to the corresponding format in \(L\).
- If \(p\) is not a polynomial, \texttt{roundcoefficients} does not do anything.
- If \(L\) contains other elements than HP, halfprecision, SG, single, D, double, DE, doubleextended, DD, doubledouble,
  QD, quad, TD and tripledouble, an error occurs.
- The coefficients in \(p\) corresponding to \(X^i\) is rounded to the format \(L[i]\). If \(L\) does not contain
  enough elements (e.g. if \texttt{length}(L) < \texttt{degree}(p)+1), a warning is displayed. However, the
  coefficients corresponding to an element of \(L\) are rounded. The trailing coefficients (that do not
  have a corresponding element in \(L\)) are kept with their own precision. If \(L\) contains too much
  elements, the trailing useless elements are ignored. In particular \(L\) may be end-elliptic in which
  case \texttt{roundcoefficients} has the natural behavior.
Example 1:

```plaintext
> p=exp(1) + x*(exp(2) + x*exp(3));
> display=binary!;
> roundcoefficients(p,[|DD,D,D|]);
1.0101101111100001010100010100010100101001010010111111101110
0101010001000000100111112 * 2^-1) + x * (1.11011001110101000101001011011011011111101111101
1001101110101111 * 2^-2) + x * (1.010000101110101111111111011111100
0100000112 * 2^-4(4));
> roundcoefficients(p,[|DD,D...|]);
1.0101101111100001010100010100010100101001010010111111101110
0101010001000000100111112 * 2^-1) + x * (1.110110011101010001010010110110110111111101111100110
01010110110101011112 * 2^-2(2) + x * (1.010000101011101111111111011111100
0100000112 * 2^-4(4));
```

Example 2:

```plaintext
> f=sin(exp(1)*x);
> display=binary!;
> f;
sin(x * (1.0101101111100001010100010100010100101001010010111111101110
1111011110001010001010010100101001010010101111011000111101110011111111101111111111110110
0110000111112 * 2^-1(1)))
> roundcoefficients(f,[|D...|]);
sin(x * (1.0101101111100001010100010100010100101001010010111111101110
1111011110001010001010010100101001010010101111011000111101110011111111101111111111110110
0110000111112 * 2^-1(1)))
```

Example 3:

```plaintext
> p=exp(1) + x*(exp(2) + x*exp(3));
> verbosity=1!;
> display=binary!;
> roundcoefficients(p,[|DD,D,D|]);
Warning: the number of the given formats does not correspond to the degree of th
e given polynomial.
Warning: the 0th coefficient of the given polynomial does not evaluate to a floa
ting-point constant without any rounding.
Will evaluate the coefficient in the current precision in floating-point before
rounding to the target format.
Warning: the 1th coefficient of the given polynomial does not evaluate to a floa
ting-point constant without any rounding.
Will evaluate the coefficient in the current precision in floating-point before
rounding to the target format.
Warning: rounding may have happened.
1.0101101111100001010100010100010100101001010010111111101110

8.157  roundcorrectly

Name: **roundcorrectly**

rounds an approximation range correctly to some precision

Library name:

```
sollya_obj_t sollya_lib_roundcorrectly(sollya_obj_t)
```

Usage:

```
roundcorrectly(range) : range → constant
```

Parameters:

- **range** represents a range in which an exact value lies

Description:

- Let **range** be a range of values, determined by some approximation process, safely bounding an unknown value **v**. The command **roundcorrectly(range)** determines a precision such that for this precision, rounding to the nearest any value in **range** yields to the same result, i.e. to the correct rounding of **v**.

  If no such precision exists, a warning is displayed and **roundcorrectly** evaluates to NaN.

Example 1:

```
> printbinary(roundcorrectly([1.010001_2; 1.0101_2]));
1.01_2
> printbinary(roundcorrectly([1.00001_2; 1.001_2]));
1_2
```

Example 2:

```
> roundcorrectly([-1; 1]);
@NaN@
```

See also: round (8.155), mantissa (8.102), exponent (8.60), precision (8.130)

8.158  roundingwarnings

Name: **roundingwarnings**

global variable controlling whether or not a warning is displayed when roundings occur.

Library names:

```
void sollya_lib_set_roundingwarnings_and_print(sollya_obj_t)
void sollya_lib_set_roundingwarnings(sollya_obj_t)
sollya_obj_t sollya_lib_get_roundingwarnings()
```

Usage:

```
roundingwarnings = activation value : on|off → void
roundingwarnings = activation value ! : on|off → void
roundingwarnings : on|off
```

Parameters:

- **activation value** controls if warnings should be shown or not

Description:

- **roundingwarnings** is a global variable. When its value is **on**, warnings are emitted in appropriate verbosity modes (see **verbosity**) when roundings occur. When its value is **off**, these warnings are suppressed.
• This mode depends on a verbosity of at least 1. See \texttt{verbosity} for more details.

• Default is \texttt{on} when the standard input is a terminal and \texttt{off} when \texttt{Sollya} input is read from a file.

Example 1:

```
> verbosity=1!;
> roundingwarnings = on;
Rounding warning mode has been activated.
> exp(0.1);
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
Warning: rounding has happened. The value displayed is a faithful rounding to 165 bits of the true result.
1.1051709180756476248117078264902466682245471947375
> roundingwarnings = off;
Rounding warning mode has been deactivated.
> exp(0.1);
1.1051709180756476248117078264902466682245471947375
```

See also:\texttt{on} \parencite{8.117}, \texttt{off} \parencite{8.116}, \texttt{verbosity} \parencite{8.189}, \texttt{midpointmode} \parencite{8.105}, \texttt{rationalmode} \parencite{8.144}, \texttt{suppressmessage} \parencite{8.175}, \texttt{unsuppressmessage} \parencite{8.187}, \texttt{showmessagenumbers} \parencite{8.163}, \texttt{getsuppressedmessages} \parencite{8.73}

8.159 RU

Name: \texttt{RU}

constant representing rounding-upwards mode.

Library names:

```
sollya_obj_t sollya_lib_round_up()
int sollya_lib_is_round_up(sollya_obj_t)
```

Description:

• \texttt{RU} is used in command \texttt{round} to specify that the value \( x \) must be rounded to the smallest floating-point number \( y \) such that \( x \leq y \).

Example 1:

```
> display=binary!;
> round(Pi,20,RU);
1.100100100001111111_2 * 2^(1)
```

See also: \texttt{RZ} \parencite{8.160}, \texttt{RD} \parencite{8.145}, \texttt{RN} \parencite{8.154}, \texttt{round} \parencite{8.155}, \texttt{ceil} \parencite{8.22}

8.160 RZ

Name: \texttt{RZ}

constant representing rounding-to-zero mode.

Library names:

```
sollya_obj_t sollya_lib_round_towards_zero()
int sollya_lib_is_round_towards_zero(sollya_obj_t)
```

Description:

• \texttt{RZ} is used in command \texttt{round} to specify that the value must be rounded to the closest floating-point number towards zero. It just consists in truncating the value to the desired format.
Example 1:

```latex
\begin{verbatim}
> display=binary!;
> round(Pi,20,RZ);
1.100100100001111101_2 * 2^(1)
\end{verbatim}
```

See also: RD 8.145, RU 8.159, RN 8.154, round 8.155, floor 8.68, ceil 8.22

### 8.161 searchgal

Name: searchgal

searches for a preimage of a function such that the rounding the image yields an error smaller than a constant.

Library name:

```latex
sollya_obj_t sollya_lib_searchgal(sollya_obj_t, sollya_obj_t, sollya_obj_t, sollya_obj_t, sollya_obj_t, sollya_obj_t)
```

Usage:

```latex
searchgal(function, start, preimage precision, steps, format, error bound) : (function, constant, integer, integer) → list
searchgal(list of functions, start, preimage precision, steps, list of format, list of error bounds) : (list, constant, integer, integer, list, list) → list
```

Parameters:

- **function** represents the function to be considered
- **start** represents a value around which the search is to be performed
- **preimage precision** represents the precision (discretization) for the eligible preimage values
- **steps** represents the binary logarithm ($\log_2$) of the number of search steps to be performed
- **format** represents the format the image of the function is to be rounded to
- **error bound** represents a upper bound on the relative rounding error when rounding the image
- **list of functions** represents the functions to be considered
- **list of formats** represents the respective formats the images of the functions are to be rounded to
- **list of error bounds** represents a upper bound on the relative rounding error when rounding the image

Description:

- The command searchgal searches for a preimage $z$ of function function or a list of functions list of functions such that $z$ is a floating-point number with preimage precision significant mantissa bits and the image $y$ of the function, respectively each image $y_i$ of the functions, rounds to format format respectively to the corresponding format in list of format with a relative rounding error less than error bound respectively the corresponding value in list of error bounds. During this search, at most $2^{steps}$ attempts are made. The search starts with a preimage value equal to start. This value is then increased and decreased by 1 ulp in precision preimage precision until a value is found or the step limit is reached.

If the search finds an appropriate preimage $z$, searchgal evaluates to a list containing this value. Otherwise, searchgal evaluates to an empty list.

Example 1:
Example 2:

```plaintext
> f = exp(x);
> s = searchgal(f,2,53,18,DD,1b-112);
> if (s != ||) then {
  v = s[0];
  print("The rounding error is 2^(",evaluate(log2(abs(DD(f)/f - 1)),v),")");
} else print("No value found");
```

The rounding error is $2^{-1.12106878438809380148206984258358542322113874177832}$

Example 3:

```plaintext
> searchgal([sin(x),cos(x)],1,53,15,[D,D],[1b-62,1b-60]);
```

See also: `round (8.155)`, `double (8.47)`, `doubledouble (8.48)`, `tripledouble (8.185)`, `evaluate (8.55)`, `worstcase (8.191)`

### 8.162 SG

Name: **SG**

short form for **single**

See also: **single (8.166)**

### 8.163 showmessagenumbers

Name: **showmessagenumbers**

activates, deactivates or inspects the state variable controlling the displaying of numbers for messages

Library names:

- `void sollya_lib_set_showmessagenumbers_and_print(sollya_obj_t)`
- `void sollya_lib_set_showmessagenumbers(sollya_obj_t)`
- `sollya_obj_t sollya_lib_get_showmessagenumbers()`

Usage:

```plaintext
showmessagenumbers = activation value : on|off → void
showmessagenumbers = activation value ! : on|off → void
showmessagenumbers : on|off
```

Parameters:

- `activation value` represents **on** or **off**, i.e. activation or deactivation

Description:

- An assignment `showmessagenumbers = activation value`, where `activation value` is one of **on** or **off**, activates respectively deactivates the displaying of numbers for warning and information messages. Every Sollya warning or information message (that is not fatal to the tool’s execution) has a message number. By default, these numbers are not displayed when a message is output. When message number displaying is activated, the message numbers are displayed together with the message. This allows the user to recover the number of a particular message in order to suppress resp. unsuppress the displaying of this particular message (see `suppressmessage` and `unsuppressmessage`).

190
• The user should be aware of the fact that message number display activation resp. deactivation through `showmessagenumbers` does not affect message displaying in general. For instance, even with message number displaying activated, messages with only displayed when general verbosity and rounding warning mode are set accordingly.

• If the assignment `showmessagenumbers = activation value` is followed by an exclamation mark, no message indicating the new state is displayed. Otherwise the user is informed of the new state of the global mode by an indication.

Example 1:

```plaintext
> verbosity = 1;
The verbosity level has been set to 1.
> 0.1;
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
0.1
> showmessagenumbers = on;
Displaying of message numbers has been activated.
> 0.1;
Warning (174): Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
0.1
> showmessagenumbers;
on
> showmessagenumbers = off!;
> 0.1;
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
0.1
```

Example 2:
> showmessagenumbers = on;
Displaying of message numbers has been activated.
> verbosity = 1;
The verbosity level has been set to 1.
> diff(0.1 * x + 1.5 * x^2);
Warning (174): Rounding occurred when converting the constant "0.1" to floating-
point with 165 bits.
If safe computation is needed, try to increase the precision.
0.1 + 3 * x
> verbosity = 0;
The verbosity level has been set to 0.
> diff(0.1 * x + 1.5 * x^2);
0.1 + 3 * x
> verbosity = 12;
The verbosity level has been set to 12.
> diff(0.1 * x + 1.5 * x^2);
Warning (174): Rounding occurred when converting the constant "0.1" to floating-
point with 165 bits.
If safe computation is needed, try to increase the precision.

Information (196): formally differentiating a function.
Information (197): differentiating the expression '0.1 * x + 1.5 * x^2'
Information (205): extraction of coefficient terms from a polynomial uses a spec-
ial algorithm for canonical forms.
Information (195): expression '0.1 + 2 * 1.5 * x' has been simplified to express-
ion '0.1 + 3 * x'.
Information (207): no Horner simplification will be performed because the given
tree is already in Horner form.
0.1 + 3 * x

See also: getsuppressedmessages [8.73], suppressmessage [8.175], unsuppressmessage [8.187],
verbosity [8.189], roundingwarnings [8.158]

8.164 simplify

Name: simplify
  simplifies an expression representing a function

Library name:
  sollya_obj_t sollya_lib_simplify(sollya_obj_t)

Usage:
  simplify(function) : function → function

Parameters:
  • function represents the expression to be simplified

Description:
  • The command simplify simplifies the expression given in argument representing the function
    function. The command simplify does not endanger the safety of computations even in Sollya’s
    floating-point environment: the function returned is mathematically equal to the function function.

  Remark that the simplification provided by simplify is not perfect: they may exist simpler equiv-
  alent expressions for expressions returned by simplify.

Example 1:

> print(simplify((6 + 2) + (5 + exp(0)) * x));
8 + 6 * x
Example 2:

```plaintext
> print(simplify((log(x - x + 1) + asin(1))));
(p1) / 2
```

Example 3:

```plaintext
> print(simplify((log(x - x + 1) + asin(1)) - (atan(1) * 2)));
(p1) / 2 - (p1) / 4 * 2
```

See also: dirtsimplify (8.44), autosimplify (8.15), rationalmode (8.144), horner (8.81)

### 8.165 sin

Name: sin

the siny function.

Library names:

- sollya_obj_t sollya_lib_sin(sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_sin(sollya_obj_t)
- #define SOLLYA_SIN(x) sollya_lib_build_function_sin(x)

Description:

- sin is the usual siny function.
- It is defined for every real number x.

See also: asin (8.10), cos (8.29), tan (8.177)

### 8.166 single

Names: single, SG

rounding to the nearest IEEE 754 single (binary32).

Library names:

- sollya_obj_t sollya_lib_single(sollya_obj_t)
- sollya_obj_t sollya_lib_single_obj()
- int sollya_lib_is_single_obj(sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_single(sollya_obj_t)
- #define SOLLYA_SG(x) sollya_lib_build_function_single(x)

Description:

- single is both a function and a constant.
- As a function, it rounds its argument to the nearest IEEE 754 single precision (i.e. IEEE754-2008 binary32) number. Subnormal numbers are supported as well as standard numbers: it is the real rounding described in the standard.
- As a constant, it symbolizes the single precision format. It is used in contexts when a precision format is necessary, e.g. in the commands round and roundcoefficients. In is not supported for implementpoly. See the corresponding help pages for examples.

Example 1:

```plaintext
> display=binary!;
> SG(0.1);
1.10011001100110011001101_2 * 2^(-4)
> SG(4.17);
1.000010101110000101001_2 * 2^(2)
> SG(1.011_2 * 2^(-1073));
0
```
8.167 sinh

Name: sinh

the hyperbolic sine function.

Library names:

sollya_obj_t sollya_lib_sinh(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_sinh(sollya_obj_t)
#define SOLLYA_SINH(x) sollya_lib_build_function_sinh(x)

Description:

- sinh is the usual hyperbolic sine function: sinh(x) = \( \frac{e^x - e^{-x}}{2} \).
- It is defined for every real number x.

See also: asinh (8.11), cosh (8.30), tanh (8.178)

8.168 sort

Name: sort

sorts a list of real numbers.

Library name:

sollya_obj_t sollya_lib_sort(sollya_obj_t)

Usage:

sort(L) : list \rightarrow list

Parameters:

- L is a list.

Description:

- If L contains only constant values, sort(L) returns the same list, but sorted in increasing order.
- If L contains at least one element that is not a constant, the command fails with a type error.
- If L is an end-elliptic list, sort will fail with an error.

Example 1:

```plaintext
> sort([1, 1]);
[1, 1]
> sort([[2, 3, 5, 2, 1, 4]]);
[1, 2, 2, 3, 4, 5]
```

8.169 sqrt

Name: sqrt

square root.

Library names:

sollya_obj_t sollya_lib_sqrt(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_sqrt(sollya_obj_t)
#define SOLLYA_SQRT(x) sollya_lib_build_function_sqrt(x)

Description:

• \texttt{sqrt} is the square root, e.g. the inverse of the function square: $\sqrt{y}$ is the unique positive $x$ such that $x^2 = y$.

• It is defined only for $x$ in $[0; +\infty]$.

8.170 string

Name: \texttt{string}

keyword representing a \texttt{string} type

Usage:

\begin{verbatim}
string : type type
\end{verbatim}

Description:

• \texttt{string} represents the \texttt{string} type for declarations of external procedures by means of \texttt{externalproc}.

Remark that in contrast to other indicators, type indicators like \texttt{string} cannot be handled outside the \texttt{externalproc} context. In particular, they cannot be assigned to variables.

See also: \texttt{externalproc (8.62)}, \texttt{boolean (8.20)}, \texttt{constant (8.28)}, \texttt{function (8.71)}, \texttt{integer (8.88)}, \texttt{list of (8.96)}, \texttt{range (8.142)}, \texttt{object (8.115)}

8.171 subpoly

Name: \texttt{subpoly}

restricts the monomial basis of a polynomial to a list of monomials

Library name:

\begin{verbatim}
sollya_obj_t sollya_lib_subpoly(sollya_obj_t, sollya_obj_t)
\end{verbatim}

Usage:

\begin{verbatim}
subpoly(polynomial, list) : (function, list) → function
\end{verbatim}

Parameters:

• \texttt{polynomial} represents the polynomial the coefficients are taken from

• \texttt{list} represents the list of monomials to be taken

Description:

• \texttt{subpoly} extracts the coefficients of a polynomial \texttt{polynomial} and builds up a new polynomial out of those coefficients associated to monomial degrees figuring in the list \texttt{list}.

If \texttt{polynomial} represents a function that is not a polynomial, subpoly returns 0.

If \texttt{list} is a list that is end-elliptic, let be \texttt{j} the last value explicitly specified in the list. All coefficients of the polynomial associated to monomials greater or equal to \texttt{j} are taken.

Example 1:

\begin{verbatim}
> p = taylor(exp(x),5,0);
> s = subpoly(p,[1,3,5]);
> print(p);
1 + x * (1 + x * (0.5 + x * (1 / 6 + x * (1 / 24 + x / 120))))
> print(s);
x * (1 + x^-2 * (1 / 6 + x^-2 / 120))
\end{verbatim}

Example 2:
> p = remez(atan(x),10,[-1,1]);
> subpoly(p,[1,3,5,...]);
\[
x \times (0.99986632941452949026018468446163586361700915018231 + x^2 \times (-0.330304785024522455936362667794059988443130926433421739 + x^2 \times (0.180159293178187564628985693637 19e-9 + x \times (-8.5156349064111377955505552996061844977507560037484e-2 + x \times (-2.71756349062775019916818769239340943524383018921799e-9 + x \times (2.08451134307111472937323991054916987245468695894998e-2 + x \times 1.1088986118112905765719966438826630081793400489512e-9))))))))
\[
\]

Example 3:

> subpoly(exp(x),[1,2,3]);
0

See also: roundcoefficients \(8.156\), taylor \(8.179\), remez \(8.149\), fpminimax \(8.69\), implement-poly \(8.84\)

### 8.172 substitute

Name: substitute

replace the occurrences of the free variable in an expression.

Library name:

sollya_obj_t sollya_lib_substitute(sollya_obj_t, sollya_obj_t)

Usage:

\[
\text{substitute}(f,g) : (\text{function, function}) \to \text{function} \\
\text{substitute}(f,t) : (\text{function, constant}) \to \text{constant}
\]

Parameters:

- \(f\) is a function.
- \(g\) is a function.
- \(t\) is a real number.

Description:

- \(\text{substitute}(f,g)\) produces the function \((f \circ g) : x \mapsto f(g(x))\).
- \(\text{substitute}(f,t)\) is the constant \(f(t)\). Note that the constant is represented by its expression until it has been evaluated (exactly the same way as if you type the expression \(f\) replacing instances of the free variable by \(t\)).
- If \(f\) is stored in a variable \(F\), the effect of the commands \(\text{substitute}(F,g)\) or \(\text{substitute}(F,t)\) is absolutely equivalent to writing \(F(g)\) resp. \(F(t)\).

Example 1:

```plaintext
> f=sin(x);
> g=cos(x);
> substitute(f,g);
sin(cos(x))
> f(g);
sin(cos(x))
```

Example 2:
> a=1;
> f=sin(x);
> substitute(f,a);
0.84147098480789650665250232163029899962256306079837
> f(a);
0.84147098480789650665250232163029899962256306079837

See also: evaluate[8.55], composepolynomials[8.26]

### 8.173 sup

**Name:** sup  
gives the upper bound of an interval.

**Library name:**  
sollya_obj_t sollya_lib_sup(sollya_obj_t)

**Usage:**  
\[
\text{sup}(I) : \text{range} \rightarrow \text{constant} \\
\text{sup}(x) : \text{constant} \rightarrow \text{constant}
\]

**Parameters:**  
- \(I\) is an interval.
- \(x\) is a real number.

**Description:**  
- Returns the upper bound of the interval \(I\). Each bound of an interval has its own precision, so this command is exact, even if the current precision is too small to represent the bound.
- When called on a real number \(x\), \(\text{sup}\) behaves like the identity.

**Example 1:**

```plaintext
> sup([1;3]);
3
> sup(5);
5
```

**Example 2:**

```plaintext
> display=binary!;
> I=[0; 0.111110000011111_2];
> sup(I);
1.1110000011111_2 * 2^(-1)
> prec=12!;
> sup(I);
1.1110000011111_2 * 2^(-1)
```

See also: inf[8.80], mid[8.104], max[8.103], min[8.106]

### 8.174 supnorm

**Name:** supnorm  
computes an interval bounding the supremum norm of an approximation error (absolute or relative) between a given polynomial and a function.

**Library name:**
Usage:

\texttt{supnorm}(p, f, I, \texttt{errorType}, \texttt{accuracy}) : (function, function, range, absolute|relative, constant) → range

Parameters:

- \texttt{p} is a polynomial.
- \texttt{f} is a function.
- \texttt{I} is an interval.
- \texttt{errorType} is the type of error to be considered: \texttt{absolute} or \texttt{relative} (see details below).
- \texttt{accuracy} is a constant that controls the relative tightness of the interval returned.

Description:

- \texttt{supnorm}(p, f, I, \texttt{errorType}, \texttt{accuracy}) tries to compute an interval bound \( r = [\ell, u] \) for the supremum norm of the error function \( \varepsilon_{\text{absolute}} = p - f \) (when \texttt{errorType} evaluates to \texttt{absolute}) or \( \varepsilon_{\text{relative}} = p/f - 1 \) (when \texttt{errorType} evaluates to \texttt{relative}), over the interval \( I \), such that \( \sup_{x \in I} \{|\varepsilon(x)|\} \subseteq r \) and \( 0 \leq |\frac{u}{\ell} - 1| \leq \texttt{accuracy} \). If \texttt{supnorm} succeeds in computing a suitable interval \( r \), which it returns, that interval is guaranteed to contain the supremum norm value and to satisfy the required quality. Otherwise, \texttt{supnorm} evaluates to \texttt{error}, displaying a corresponding error message. These failure cases are rare and basically happen only for functions which are too complicated.

- Roughly speaking, \texttt{supnorm} is based on \texttt{taylorform} to obtain a higher degree polynomial approximation for \( f \). This process is coupled with an a posteriori validation of a potential supremum norm upper bound. The validation is based on showing a certain polynomial the problem gets reduced to does not vanish. In cases when this process alone does not succeed, for instance because \texttt{taylorform} is unable to compute a sufficiently good approximation to \( f \), \texttt{supnorm} falls back to bisecting the working interval until safe supremum norm bounds can be computed with the required accuracy or until the width of the subintervals becomes less than \( \texttt{diam} \) times the original interval \( I \), in which case \texttt{supnorm} fails.

- The algorithm used for \texttt{supnorm} is quite complex, which makes it impossible to explain it here in further detail. Please find a complete description in the following article:

Sylvain Chevillard, John Harrison, Mioara Joldes, Christoph Lauter
Efficient and accurate computation of upper bounds of approximation errors
Journal of Theoretical Computer Science (TCS), 2010
LIP Research Report number RR LIP2010-2
http://prunel.ccsd.cnrs.fr/ensl-00445343/fr/

- In practical cases, \texttt{supnorm} should be able to automatically handle removable discontinuities that relative errors might have. This means that usually, if \( f \) vanishes at a point \( x_0 \) in the interval considered, the approximation polynomial \( p \) is designed such that it also vanishes at the same point with a multiplicity large enough. Hence, although \( f \) vanishes, \( \varepsilon_{\text{relative}} = p/f - 1 \) may be defined by continuous extension at such points \( x_0 \), called removable discontinuities (see Example 3).

Example 1:

\begin{verbatim}
> p = remez(exp(x), 5, [-1;1]);
> midpointmode=on!;
> supnorm(p, exp(x), [-1;1], absolute, 2^(-40));
0.45205613967~0/2~e-4
\end{verbatim}
Example 2:

```plaintext
> prec=200!
> midpointmode=on!
> d = [1;2];
> f = exp(cos(x)^2 + 1);
> p = remez(1,15,d,1/f,1e-40);
> theta=1b-60;
> prec=default!
> mode=relative;
> supnorm(p,f,d,mode,theta);
0.30893006200251428~5/6~e-13
```

Example 3:

```plaintext
> midpointmode=on!
> mode=relative;
> theta=1b-135;
> d = [-1b-2;1b-2];
> f = expm1(x);
> p = x * (1 + x * (2097145 * 2^(-22) + x * (349527 * 2^(-21) + x * (87609 * 2^(-21) + x * 4369 * 2^(-19)))));
> theta=1b-40;
> supnorm(p,f,d,mode,theta);
0.98349131972~2/3~e-7
```

### 8.175 suppressmessage

Name: `suppressmessage`

suppresses the displaying of messages with a certain number

Library name:

`void sollya_lib_suppressmessage(sollya_obj_t, ...);`

Usage:

```plaintext
suppressmessage(msg num 1, ..., msg num n) : (integer, ..., integer) → void
suppressmessage(msg list) : list → void
```

Parameters:

- `msg num 1` thru `msg num n` represent the numbers of `n` messages to be suppressed
- `msg list` represents a list with numbers of messages to be suppressed

Description:

- The `suppressmessage` command allows particular warning and information messages to be suppressed from message output, while maintaining global verbosity levels (see `verbosity`) high. Every Sollya warning or information message (that is not fatal to the tool’s execution) has a message number. When these message numbers `msg num 1` thru `msg num n` are given to `suppressmessage`, the corresponding message are no longer displayed. The `unsuppressmessage` command reverts this suppression from output for a particular message.
- Instead of giving `suppressmessage` several message numbers `msg num 1` thru `msg num n` or calling `suppressmessage` several times, it is possible to give a whole list `msg list` of message numbers to `suppressmessage`. 199
• The user should be aware that `suppressmessage` presents sticky behavior for the warning and information messages suppressed from output. This means that even if subsequent calls to `suppressmessage` occur, a message suppressed by a call to `suppressmessage` stays suppressed until it is unsuppressed using `unsuppressmessage` or the tool is restarted. This behavior distinguishes message suppression from other global states of the Sollya tool. The user may use `getsuppressedmessages` to obtain a list of currently suppressed messages.

• When `suppressmessage` is used on message numbers that do not exist in the current version of the tool, a warning is displayed. The call has no other effect though.

Example 1:

```plaintext
> verbosity = 1;
The verbosity level has been set to 1.
> 0.1;
Warning: Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
0.1
> suppressmessage(174);
> 0.1;
0.1
> suppressmessage(407);
> 0.1;
0.1
> verbosity = 12;
The verbosity level has been set to 12.
> showmessenger = on;
Displaying of message numbers has been activated.
> diff(exp(x * 0.1));
Information (196): formally differentiating a function.
Information (197): differentiating the expression 'exp(x * 0.1)'
Information (204): extraction of coefficient terms from a polynomial uses a special algorithm for Horner forms.
Information (207): no Horner simplification will be performed because the given tree is already in Horner form.
exp(x * 0.1) * 0.1
> suppressmessage(207, 196);
> diff(exp(x * 0.1));
Information (197): differentiating the expression 'exp(x * 0.1)'
Information (204): extraction of coefficient terms from a polynomial uses a special algorithm for Horner forms.
exp(x * 0.1) * 0.1
> unsuppressmessage(174);
> 0.1;
Warning (174): Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
0.1
```

Example 2:
verbosity = 12;
The verbosity level has been set to 12.
> showmessagenumbers = on;
Displaying of message numbers has been activated.
> diff(exp(x * 0.1));
Warning (174): Rounding occurred when converting the constant "0.1" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
Information (196): formally differentiating a function.
Information (197): differentiating the expression 'exp(x * 0.1)'
Information (204): extraction of coefficient terms from a polynomial uses a special algorithm for Horner forms.
Information (207): no Horner simplification will be performed because the given tree is already in Horner form.
exp(x * 0.1) * 0.1
> suppressmessage([| 174, 207, 196 |]);
> diff(exp(x * 0.1));
Information (197): differentiating the expression 'exp(x * 0.1)'
Information (204): extraction of coefficient terms from a polynomial uses a special algorithm for Horner forms.
exp(x * 0.1) * 0.1

8.176 tail
Name: tail
   gives the tail of a list.
Library name:
   sollya_obj_t sollya_lib_tail(sollya_obj_t)
Usage:
   tail(L) : list → list
Parameters:
   • L is a list.
Description:
   • tail(L) returns the list L without its first element.
   • If L is empty, the command will fail with an error.
   • tail can also be used with end-elliptic lists. In this case, the result of tail is also an end-elliptic list.
Example 1:

> tail([[1,2,3]]);
[[2, 3]]
> tail([[1,2...]]);
[[2...]]

See also: head (8.77)
8.177 tan

Name: tan
the tangent function.

Library names:
sollya_obj_t sollya_lib_tan(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_tan(sollya_obj_t)
#define SOLLYA_TAN(x) sollya_lib_build_function_tan(x)

Description:
• tan is the tangent function, defined by \( \tan(x) = \frac{\sin(x)}{\cos(x)} \).
• It is defined for every real number \( x \) that is not of the form \( n\pi + \frac{\pi}{2} \) where \( n \) is an integer.

See also: atan (8.12), cos (8.29), sin (8.165)

8.178 tanh

Name: tanh
the hyperbolic tangent function.

Library names:
sollya_obj_t sollya_lib_tanh(sollya_obj_t)
sollya_obj_t sollya_lib_build_function_tanh(sollya_obj_t)
#define SOLLYA_TANH(x) sollya_lib_build_function_tanh(x)

Description:
• tanh is the hyperbolic tangent function, defined by \( \tanh(x) = \frac{\sinh(x)}{\cosh(x)} \).
• It is defined for every real number \( x \).

See also: atanh (8.13), cosh (8.30), sinh (8.167)

8.179 taylor

Name: taylor
computes a Taylor expansion of a function in a point

Library name:
sollya_obj_t sollya_lib_taylor(sollya_obj_t, sollya_obj_t, sollya_obj_t)

Usage:
\[ \text{taylor}(\text{function}, \text{degree}, \text{point}) : (\text{function}, \text{integer}, \text{constant}) \rightarrow \text{function} \]

Parameters:
• function represents the function to be expanded
• degree represents the degree of the expansion to be delivered
• point represents the point in which the function is to be developed

Description:
• The command taylor returns an expression that is a Taylor expansion of function function in point point having the degree degree.

Let \( f \) be the function function, \( t \) be the point point and \( n \) be the degree degree. Then, tay-
lor(function, degree, point) evaluates to an expression mathematically equal to
\[
\sum_{i=0}^{n} \frac{f^{(i)}(t)}{i!} x^i.
\]
In other words, if \( p(x) \) denotes the polynomial returned by \texttt{taylor}, \( p(x-t) \) is the Taylor polynomial of degree \( n \) of \( f \) developed at point \( t \).

Remark that \texttt{taylor} evaluates to 0 if the degree \textit{degree} is negative.

Example 1:
\[
> \text{print(taylor(exp(x),3,1))};
\]
\[
\exp(1) + x \cdot (\exp(1) + x \cdot (0.5 \cdot \exp(1) + x \cdot \exp(1) / 6))
\]

Example 2:
\[
> \text{print(taylor(asin(x),7,0))};
\]
\[
x \cdot (1 + x^{-2} \cdot (1 / 6 + x^{-2} \cdot (9 / 120 + x^{-2} * 225 / 5040)))
\]

Example 3:
\[
> \text{print(taylor(erf(x),6,0))};
\]
\[
x \cdot (1 / \sqrt{(\pi) / 4} + x^2 \cdot ((\sqrt{(\pi) / 4)} / 6 + x^2 \cdot (\sqrt{(\pi) / 4)} / 4 / (\pi) * (-2)) / 6 + x^2 \cdot (\sqrt{(\pi) / 4)} / 4 / (\pi) * 12) / 120))
\]

See also: \texttt{remez [8.149]}, \texttt{fpminimax [8.69]}, \texttt{taylorform [8.180]}

8.180 \textbf{taylorform}

Name: \texttt{taylorform}

computes a rigorous polynomial approximation (polynomial, interval error bound) for a function, based on Taylor expansions.

Library names:

\begin{verbatim}
sollya_obj_t sollya_lib_taylorform(sollya_obj_t, sollya_obj_t, sollya_obj_t, ...)
sollya_obj_t sollya_lib_v_taylorform(sollya_obj_t, sollya_obj_t, sollya_obj_t, va_list)
\end{verbatim}

Usage:

\begin{verbatim}
taylorform(f, n, x0, I, errorType) : (function, integer, constant, range, absolute\text{or}relative) \rightarrow list
taylorform(f, n, x0, l, errorType) : (function, integer, range, range, absolute\text{or}relative) \rightarrow list
taylorform(f, n, x0, errorType) : (function, integer, constant, absolute\text{or}relative) \rightarrow list
taylorform(f, n, x0, errorType) : (function, integer, range, absolute\text{or}relative) \rightarrow list
\end{verbatim}

Parameters:

\begin{itemize}
  \item \( f \) is the function to be approximated.
  \item \( n \) is the degree of the polynomial that must approximate \( f \).
  \item \( x_0 \) is the point (it can be a real number or an interval) where the Taylor expansion of the function is to be considered.
  \item \( I \) is the interval over which the function is to be approximated. If this parameter is omitted, the behavior is changed (see detailed description below).
  \item \textit{errorType} (optional) is the type of error to be considered. See the detailed description below. Default is \texttt{absolute}.
\end{itemize}

Description:

\begin{itemize}
  \item \textbf{WARNING: taylorform} is a certified command, not difficult to use but not completely straightforward to use either. In order to be sure to use it correctly, the reader is invited to carefully read this documentation entirely.
\end{itemize}
• **taylorform** computes an approximation polynomial and an interval error bound for function $f$. More precisely, it returns a list $L = [p, coeffErrors, \Delta]$ where:

- $p$ is an approximation polynomial of degree $n$ such that $p(x - x_0)$ is roughly speaking a numerical Taylor expansion of $f$ at the point $x_0$.
- $coeffErrors$ is a list of $n + 1$ intervals. Each interval $coeffErrors[i]$ contains an enclosure of all the errors accumulated when computing the $i$-th coefficient of $p$.
- $\Delta$ is an interval that provides a bound for the approximation error between $p$ and $f$. Its significance depends on the errorType considered.

• The polynomial $p$ and the bound $\Delta$ are obtained using Taylor Models principles.

• Please note that $x_0$ can be an interval. In general, it is meant to be a small interval approximating a non representable value. If $x_0$ is given as a constant expression, it is first numerically evaluated (leading to a faithful rounding $\tilde{x}_0$ at precision $prec$), and it is then replaced by the (exactly representable) point-interval $[\tilde{x}_0, \tilde{x}_0]$. In particular, it is not the same to call `taylorform` with $x_0 = \pi$ and with $x_0 = [\pi]$, for instance. In general, if the point around which one desires to compute the polynomial is not exactly representable, one should preferably use a small interval for $x_0$.

• More formally, the mathematical property ensured by the algorithm may be stated as follows. For all $\xi_0$ in $x_0$, there exist (small) values $\varepsilon_i \in coeffErrors[i]$ such that:

  If errorType is absolute, $\forall x \in I$, $\exists \delta \in \Delta$, $f(x) - p(x - \xi_0) = \sum_{i=0}^{n} \varepsilon_i (x - \xi_0)^i + \delta$.

  If errorType is relative, $\forall x \in I$, $\exists \delta \in \Delta$, $f(x) - p(x - \xi_0) = \sum_{i=0}^{n} \varepsilon_i (x - \xi_0)^i + \delta (x - \xi_0)^{n+1}$.

• It is also possible to use a large interval for $x_0$, though it is not obvious to give an intuitive sense to the result of `taylorform` in that case. A particular case that might be interesting is when $x_0 = I$ in relative mode. In that case, denoting by $p_i$ the coefficient of $p$ of order $i$, the interval $p_i + coeffError[i]$ gives an enclosure of $f^{(i)}(I)/i!$. However, the command `autodiff` is more convenient for computing such enclosures.

• When the interval $I$ is not given, the approximated Taylor polynomial is computed but no remainder is produced. In that case the returned list is $L = [p, coeffErrors]$.

• The relative case is especially useful when functions with removable singularities are considered. In such a case, this routine is able to compute a finite remainder bound, provided that the expansion point given is the problematic removable singularity point.

• The algorithm does not guarantee that by increasing the degree of the approximation, the remainder bound will become smaller. Moreover, it may even become larger due to the dependency phenomenon present with interval arithmetic. In order to reduce this phenomenon, a possible solution is to split the definition domain $I$ into several smaller intervals.

• The command `taylor` also computes a Taylor polynomial of a function. However it does not provide a bound on the remainder. Besides, `taylor` is a somehow symbolic command: each coefficient of the Taylor polynomial is computed exactly and returned as an expression tree exactly equal to theoretical value. It is henceforth much more inefficient than `taylorform` and `taylorform` should be preferred if only numerical (yet safe) computations are required. The same difference exists between commands `diff` and `autodiff`.

**Example 1:**
Example 2:

```plaintext
> TL = taylorform(sin(x)/x, 10, 0, [-1,1], relative);
> p = TL[0];
> Delta = TL[2];
> errors = TL[1];
> for epsi in errors do epsi;

### 8.181 taylorrecursions

Name: `taylorrecursions`  
controls the number of recursion steps when applying Taylor’s rule.

Library names:

- `void sollya_lib_set_taylorrecursions_and_print(sollya_obj_t)`
- `void sollya_lib_set_taylorrecursions(sollya_obj_t)`
- `sollya_obj_t sollya_lib_get_taylorrecursions()`

Usage:

```plaintext
taylorrecursions = n : integer → void
taylorrecursions = n ! : integer → void
taylorrecursions : integer
```

Parameters:

- `n` represents the number of recursions

Description:

- `taylorrecursions` is a global variable. Its value represents the number of steps of recursion that are used when applying Taylor’s rule. This rule is applied by the interval evaluator present in the core of Sollya (and particularly visible in commands like `infnorm`).

- To improve the quality of an interval evaluation of a function \( f \), in particular when there are problems of decorrelation), the evaluator of Sollya uses Taylor’s rule:  
  \[
  f([a,b]) \subseteq f(m) + [a - m, b - m] \cdot f'([a, b]) \quad \text{where} \quad m = \frac{a + b}{2}.
  \]
  This rule can be applied recursively. The number of step in this recursion process is controlled by `taylorrecursions`.

- Setting `taylorrecursions` to 0 makes Sollya use this rule only once; setting it to 1 makes Sollya use the rule twice, and so on. In particular: the rule is always applied at least once.

Example 1:
\[
> f = \exp(x);
> p = \text{remez}(f, 3, [0; 1]);
> \text{taylorrecursions}=0;
\]
The number of recursions for Taylor evaluation has been set to 0.
\[
> \text{evaluate}(f-p, [0; 1]);
[-0.46839364816268368775174657814112460243249079671039; 0.469477817546468820647293019728402934746974652584671]
> \text{taylorrecursions}=1;
\]
The number of recursions for Taylor evaluation has been set to 1.
\[
> \text{evaluate}(f-p, [0; 1]);
[-0.138131114954063839905475752120786856031651747712954; 0.1392152843378483582665937126369160106890747684927]
\]
See also: hopitalrecursions (8.80), evaluate (8.55), infnorm (8.87)

8.182 TD
Name: TD
short form for tripledouble
See also: tripledouble (8.18)

8.183 time
Name: time
procedure for timing Sollya code.

Usage:

\[
time(code) : code \rightarrow constant
\]

Parameters:

- code is the code to be timed.

Description:

- time permits timing a Sollya instruction, resp. a begin-end block of Sollya instructions. The timing value, measured in seconds, is returned as a Sollya constant (and not merely displayed as for timing). This permits performing computations of the timing measurement value inside Sollya.

- The extended nop command permits executing a defined number of useless instructions. Taking the ratio of the time needed to execute a certain Sollya instruction and the time for executing a nop therefore gives a way to abstract from the speed of a particular machine when evaluating an algorithm’s performance.

Example 1:

\[
> t = time(p=\text{remez}(\sin(x), 10, [-1; 1]));
> \text{write}(t,"s were spent computing p = ",p,"\n");
0.2140609999999999997438160370677451282724699258804s were spent computing p =

\]
Example 2:

```latex
> write(time({ p=remez(sin(x),10,[-1;1]); write("The error is 2^-", log2(dirtyinf
fnorm(p-sin(x),[-1;1]), ")\n")); }), 
" s were spent\n
The error is 2^- (log2(2.396019794465248664952828993348207029480807497e-1) 0.36765199999999999999634105874992237115200459957 s were spent
```

Example 3:

```latex
> t = time(bashexecute("sleep 10"));
> write("(t-10),"s of execution overhead.\n
2.57999999999986083124895085347816348075866699219e-3s of execution overhead.
```

Example 4:

```latex
> ratio := time(p=remez(sin(x),10,[-1;1]))/time(nop(10));
> write("This ratio = ", ratio, ", ratio, " should somehow be independent of the type of m
achine.\n
This ratio = 6.192493735066146046665145865139082858763724855621 should somehow
be independent of the type of machine.
```

See also: timing [8.184], nop [8.111]

8.184 timing

Name: timing
global variable controlling timing measures in Sollya.

Library names:
void sollya_lib_set_timing_and_print(sollya_obj_t)
void sollya_lib_set_timing(sollya_obj_t)
sollya_obj_t sollya_lib_get_timing()

Usage:

```
timing = activation value : on/off → void
timing = activation value ! : on/off → void
timing : on/off
```

Parameters:

- `activation value` controls if timing should be performed or not

Description:

- `timing` is a global variable. When its value is `on`, the time spent in each command is measured and displayed (for verbosity levels higher than 1).

Example 1:

```latex
> verbosity=1!;
> timing=on;
Timing has been activated.
> p=remez(sin(x),10,[-1;1]);

Information: assignment spent 195 ms
Information: full execution of the last parse chunk spent 212 ms
```
8.185 tripledouble

Names: tripledouble, TD
represents a number as the sum of three IEEE doubles.

Library names:
- sollya_obj_t sollya_lib_triple_double(sollya_obj_t)
- sollya_obj_t sollya_lib_triple_double_obj()
- int sollya_lib_is_triple_double_obj(sollya_obj_t)
- sollya_obj_t sollya_lib_build_function_triple_double(sollya_obj_t)
- #define SOLLYA_TD(x) sollya_lib_build_function_triple_double(x)

Description:
- **tripledouble** is both a function and a constant.
- As a function, it rounds its argument to the nearest number that can be written as the sum of three double precision numbers.
- The algorithm used to compute tripledouble(x) is the following: let \( x_h = \text{double}(x) \), let \( x_m = \text{double}(x - x_h) \) and let \( x_l = \text{double}(x - x_h - x_m) \). Return the number \( x_h + x_m + x_l \). Note that if the current precision is not sufficient to represent exactly \( x_h + x_m + x_l \), a rounding will occur and the result of tripledouble(x) will be useless.
- As a constant, it symbolizes the triple-double precision format. It is used in contexts when a precision format is necessary, e.g. in the commands roundcoefficients and implementpoly. See the corresponding help pages for examples.

Example 1:

```plaintext
> verbosity=1!
> a = 1 + 2^(-55) + 2^(-115);
> TD(a);
1.00000000000000002775557561562891353466491600711096
> prec=110!;
> TD(a);
1.00000000000000002775557561562891353
```

See also: halfprecision (8.76), single (8.166), double (8.47), doubleextended (8.49), doubledouble (8.48), quad (8.140), roundcoefficients (8.156), implementpoly (8.84), fpminimax (8.69), print-expansion (8.134)

8.186 true

Name: true
the boolean value representing the truth.

Library names:
- sollya_obj_t sollya_lib_true()
- int sollya_lib_is_true(sollya_obj_t)

Description:
- **true** is the usual boolean value.

Example 1:

```plaintext
> true && false;
false
> 2>1;
true
```
8.187  unsuppressmessage

Name: unsuppressmessage
unsuppresses the displaying of messages with a certain number

Library name:
void sollya_lib_unsuppressmessage(sollya_obj_t, ...);

Usage:

unsuppressmessage(msg num 1, ..., msg num n) : (integer, ..., integer) → void
unsuppressmessage(msg list) : list → void

Parameters:

• msg num 1 thru msg num n represent the numbers of n messages to be suppressed
• msg list represents a list with numbers of messages to be suppressed

Description:

• The unsuppressmessage command allows particular warning and information messages that have been suppressed from message output to be unsuppressed, i.e. activated for display again. Every Sollya warning or information message (that is not fatal to the tool’s execution) has a message number. When these message numbers msg num 1 thru msg num n are given to unsuppressmessage, the corresponding message are displayed again, as they are by default at according verbosity levels. Actually, the unsuppressmessage command just reverts the effects of the suppressmessage command.

• Instead of giving unsuppressmessage several message numbers msg num 1 thru msg num n or calling unsuppressmessage several times, it is possible to give a whole list msg list of message numbers to unsuppressmessage.

• The user should be aware that unsuppressmessage presents sticky behavior for the warning and information messages suppressed from output. In fact, unsuppressmessage just unsuppresses the warning or information messages given in argument. All other suppressed messages stay suppressed until they get unsuppressed by subsequent calls to unsuppressmessage or the Sollya tool is restarted. This behavior distinguishes message suppression from other global states of the Sollya tool. The user may use getsuppressedmessages to obtain a list of currently suppressed messages. In particular, in order to unsuppressed all currently suppressed warning or information messages, the user may feed the output of getsuppressedmessages (a list) into unsuppressmessage.

• The user should also note that unsuppressing warning or information messages with unsuppressmessage just reverts the effects of the suppressmessage command but that other conditions exist that affect the actual displaying of a message, such as global verbosity (see verbosity) and modes like rounding warnings (see roundingwarnings). A message will not just get displayed because it was unsuppressed with unsuppressmessage.

• When unsuppressmessage is used on message numbers that do not exist in the current version of the tool, a warning is displayed. The call has no other effect though.

Example 1:
Example 2:

```plaintext
> verbosity = 12;
The verbosity level has been set to 12.
> showmagemenumber = on;
Displaying of message numbers has been activated.
> diff(exp(x * 0.1));
Warning (174): Rounding occurred when converting the constant "0.1" to floating-point
with 165 bits.
If safe computation is needed, try to increase the precision.
exp(x * 0.1)
> suppressmessage(174);
> 0.1;
0.1
> suppressmessage(174);
> 0.1;
0.1
```

Example 3:

```plaintext
> verbosity = 12;
The verbosity level has been set to 12.
> showmagemenumber = on;
Displaying of message numbers has been activated.
> suppressmessage(207, 387, 390, 391, 196, 195, 197, 205);
> unsuppressedmessages();

See also: getsuppressedmessages [8.73], suppressmessage [8.175], unsuppressedmessage [8.187],
verbosity [8.189], roundingwarnings [8.158]
```
8.188 var

Name: var
declaration of a local variable in a scope

Usage:

\texttt{var \ identifier1, identifier2, \ldots, identifierN : void}

Parameters:

- \texttt{identifier1, identifier2, \ldots, identifierN} represent variable identifiers

Description:

- The keyword \texttt{var} allows for the declaration of local variables \texttt{identifier1} through \texttt{identifierN} in a begin-end-block (\{\}-block). Once declared as a local variable, an identifier will shadow identifiers declared in higher scopes and undeclared identifiers available at top-level.

Variable declarations using \texttt{var} are only possible in the beginning of a begin-end-block. Several \texttt{var} statements can be given. Once another statement is given in a begin-end-block, no more \texttt{var} statements can be given.

Variables declared by \texttt{var} statements are dereferenced as \texttt{error} until they are assigned a value.

Example 1:

```plaintext
> exp(x);
exp(x)
> a = 3;
> \{var a, b; a=5; b=3; \{var a; var b; b = true; a = 1; a; b;\}; a; b;\};
 1
true
5
3
> a;
3
```

See also: error (8.54), proc (8.137)

8.189 verbosity

Name: verbosity
global variable controlling the amount of information displayed by commands.

Library names:

\begin{verbatim}
void sollya_lib_set_verbosity_and_print(sollya_obj_t)
void sollya_lib_set_verbosity(sollya_obj_t)
sollya_obj_t sollya_lib_get_verbosity()
\end{verbatim}

Usage:

\texttt{verbosity = n : integer \rightarrow void}
\texttt{verbosity = n ! : integer \rightarrow void}
\texttt{verbosity : integer}

Parameters:

- \texttt{n} controls the amount of information to be displayed

Description:

- \texttt{verbosity} accepts any integer value. At level 0, commands do not display anything on standard output. Note that very critical information may however be displayed on standard error.

212
• Default level is 1. It displays important information such as warnings when roundings happen.
• For higher levels more information is displayed depending on the command.

Example 1:

```
> verbosity=0!
> 1.2+toto
error
> verbosity=1!
> 1.2+toto
Warning: Rounding occurred when converting the constant "1.2" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
error
> verbosity=2!
> 1.2+toto
Warning: Rounding occurred when converting the constant "1.2" to floating-point with 165 bits.
If safe computation is needed, try to increase the precision.
Warning: at least one of the given expressions or a subexpression is not correctly typed
or its evaluation has failed because of some error on a side-effect.
Information: the expression or a partial evaluation of it has been the following :
(1.199999999999999999999999999999999999999999999999 + ("toto")
```

See also: roundingwarnings (8.158), suppressmessage (8.175), unsuppressmessage (8.187), showmessages (8.163), getsuppressedmessages (8.73)

8.190 void

Name: void
the functional result of a side-effect or empty argument resp. the corresponding type

Library names:
  sollya_obj_t sollya_lib_void()
  int sollya_lib_is_void(sollya_obj_t)

Usage:
  void : void | type type

Description:
• The variable void represents the functional result of a side-effect or an empty argument. It is used only in combination with the applications of procedures or identifiers bound through externalproc to external procedures.

The void result produced by a procedure or an external procedure is not printed at the prompt. However, it is possible to print it out in a print statement or in complex data types such as lists.

The void argument is implicit when giving no argument to a procedure or an external procedure when applied. It can nevertheless be given explicitly. For example, suppose that foo is a procedure or an external procedure with a void argument. Then foo() and foo(void) are correct calls to foo. Here, a distinction must be made for procedures having an arbitrary number of arguments. In
this case, an implicit \texttt{void} as the only parameter to a call of such a procedure gets converted into an empty list of arguments, an explicit \texttt{void} gets passed as-is in the formal list of parameters the procedure receives.

- \texttt{void} is used also as a type identifier for \texttt{externalproc}. Typically, an external procedure taking \texttt{void} as an argument or returning \texttt{void} is bound with a signature \texttt{void} $\rightarrow$ some type or some type $\rightarrow$ \texttt{void}. See \texttt{externalproc} for more details.

Example 1:

```
> print(void);
void
> void;
```

Example 2:

```
> hey = proc() { print("Hello world.");
> hey;
proc()
{
  print("Hello world.");
  return void;
}
> hey();
Hello world.
> hey(void);
Hello world.
> print(hey());
Hello world.
void
```

Example 3:

```
> bashexecute("gcc -fPIC -Wall -c externalprocvoidexample.c");
> bashexecute("gcc -fPIC -shared -o externalprocvoidexample externalprocvoidexample.o");
> externalproc(foo, "./externalprocvoidexample", void $\rightarrow$ void);
> foo;
foo(void) $\rightarrow$ void
> foo();
Hello from the external world.
> foo(void);
Hello from the external world.
> print(foo());
Hello from the external world.
void
```

Example 4:

```
> procedure blub(L = ...){ print("Argument list:", L); }
> blub(1);
Argument list: [[1]]
> blub();
Argument list: [ ]
> blub(void);
Argument list: [void]
```

See also: \texttt{error (8.54), proc (8.137), externalproc (8.62)}
8.191 worstcase

Name: worstcase
searches for hard-to-round cases of a function

Library names:
void sollya_lib_worstcase(sollya_obj_t, sollya_obj_t, sollya_obj_t,
sollya_obj_t, sollya_obj_t, ...)
void sollya_lib_v_worstcase(sollya_obj_t, sollya_obj_t, sollya_obj_t,
sollya_obj_t, sollya_obj_t, va_list)

Usage:
worstcase(function, preimage precision, preimage exponent range, image precision, error bound) : (function, integer, range, integer, constant) → void
worstcase(function, preimage precision, preimage exponent range, image precision, error bound, filename) : (function, integer, range, integer, constant, string) → void

Parameters:
• function represents the function to be considered
• preimage precision represents the precision of the preimages
• preimage exponent range represents the exponents in the preimage format
• image precision represents the precision of the format the images are to be rounded to
• error bound represents the upper bound for the search w.r.t. the relative rounding error
• filename represents a character sequence containing a filename

Description:
• The worstcase command is deprecated. It searches for hard-to-round cases of a function. The command searchgal has a comparable functionality.

Example 1:

```
> worstcase(exp(x),24,[1,2],24,1b-26);
prec = 165
x = 1.9999998079071044921875 f(x) = 7.3890552520751953125 eps = 4.59986014234669596184695493764120138001954979037e-9 = 2^-27.695763
x = 2 f(x) = 7.38905620574951171875 eps = 1.4456360874967301812222
8379395533417878125150587072e-8 = 2^-26.043720
```

See also: round [8.155], searchgal [8.161], evaluate [8.55]

8.192 write

Name: write
prints an expression without separators

Usage:
write(expr1,...,exprn) : (any type,..., any type) → void
write(expr1,...,exprn) > filename : (any type,..., any type, string) → void
write(expr1,...,exprn) >> filename : (any type,...,any type, string) → void

Parameters:
• expr represents an expression
• `filename` represents a character sequence indicating a file name

Description:

• `write(expr1,...,exprn)` prints the expressions `expr1` through `exprn`. The character sequences corresponding to the expressions are concatenated without any separator. No newline is displayed at the end. In contrast to `print`, `write` expects the user to give all separators and newlines explicitly.

If a second argument `filename` is given after a single ">", the displaying is not output on the standard output of Sollya but if in the file `filename` that get newly created or overwritten. If a double """" is given, the output will be appended to the file `filename`.

The global variables `display`, `midpointmode` and `fullparentheses` have some influence on the formatting of the output (see `display`, `midpointmode` and `fullparentheses`).

Remark that if one of the expressions `expri` given in argument is of type `string`, the character sequence `expri` evaluates to is displayed. However, if `expri` is of type list and this list contains a variable of type `string`, the expression for the list is displayed, i.e. all character sequences get displayed surrounded by quotes (" "). Nevertheless, escape sequences used upon defining character sequences are interpreted immediately.

Example 1:

```plaintext
> write(x + 2 + exp(sin(x)));  
> write("Hello\n");  
x + 2 + exp(sin(x))Hello  
> write("Hello","world\n");  
Hello world  
> write("Hello","you", 4 + 3, "other persons.\n");  
Hello you7other persons.
```

Example 2:

```plaintext
> write("Hello","\n");  
Hello  
> write([|"Hello"|],"\n");  
[|"Hello"|]  
> s = "Hello";  
> write(s,[|s|],"\n");  
Hello[|"Hello"|]  
> t = "Hello\tyou";  
> write(t,[|t|],"\n");  
Hello you[|"Hello\tyou"|]
```

Example 3:

```plaintext
> write(x + 2 + exp(sin(x))) > "foo.sol";  
> readfile("foo.sol");  
x + 2 + exp(sin(x))
```

Example 4:

```plaintext
> write(x + 2 + exp(sin(x))) >> "foo.sol";
```

9 Appendix: interval arithmetic philosophy in Sollya

Although it is currently based on the MPFI library, Sollya has its own way of interpreting interval arithmetic when infinities or NaN occur, or when a function is evaluated on an interval containing points out of its domain, etc. This philosophy may differ from the one applied in MPFI. It is also possible that the behavior of Sollya does not correspond to the behavior that one would expect, e.g. as a natural consequence of the IEEE-754 standard.

The topology that we consider is always the usual topology of $\mathbb{R} = \mathbb{R} \cup \{-\infty, +\infty\}$. For any function, if one of its arguments is empty (respectively NaN), we return empty (respectively NaN).

9.1 Univariate functions

Let $f$ be a univariate basic function and $I$ an interval. We denote by $J$ the result of the interval evaluation of $f$ over $I$ in Sollya. If $I$ is completely included in the domain of $f$, $J$ will usually be the smallest interval (at the current precision) containing the exact image $f(I)$. However, in some cases, it may happen that $J$ is not as small as possible. It is guaranteed however, that $J$ tends to $f(I)$ when the precision of the tool tends to infinity.

When $f$ is not defined at some point $x$ but is defined on a neighborhood of $x$, we consider that the “value” of $f$ at $x$ is the convex hull of the limit points of $f$ around $x$. For instance, consider the evaluation of $f = \tan$ on $[0, \pi]$. It is not defined at $\pi/2$ (and only at this point). The limit points of $f$ around $\pi/2$ are $-\infty$ and $+\infty$, so, we return $[-\infty, \infty]$. Another example: $f = \sin$ on $[+\infty]$. The function has no limit at this point, but all points of $[-1, 1]$ are limit points. So, we return $[-1, 1]$.

Finally, if $I$ contains a subinterval on which $f$ is not defined, we return $[\text{NaN}, \text{NaN}]$ (example: $\sqrt{-1, 2}$).

9.2 Bivariate functions

Let $f$ be a bivariate function and $I_1$ and $I_2$ be intervals. If $I_1 = [x]$ and $I_2 = [y]$ are both point-intervals, we return the convex hull of the limit points of $f$ around $(x, y)$ if it exists. In particular, if $f$ is defined at $(x, y)$ we return its value (or a small interval around it, if it is not exactly representable). As an example $[1/[+\infty]$ returns $0$. Also, $[1]/[0]$ returns $[-\infty, +\infty]$ (note that Sollya does not consider signed zeros).

If it is not possible to give a meaning to the expression $f(I_1, I_2)$, we return NaN: for instance $[0]/[0]$ or $[0] *[+\infty]$. If one and only one of the intervals is a point-interval (say $I_1 = [x]$), we consider the partial function $g : y \mapsto f(x, y)$ and return the value that would be obtained when evaluating $g$ on $I_2$. For instance, in order to evaluate $[0]/I_2$, we consider the function $g$ defined for every $y \neq 0$ by $g(y) = 0/y = 0$. Hence, $g(I_2) = [0]$ (even if $I_2$ contains 0, by the argument of limit-points). In particular, please note that $[0]/[-1, 1]$ returns $0$, even though $[0]/[0]$ returns NaN. This rule even holds when $g$ can only be defined as limit points: for instance, in the case $I_1/[0]$ we consider $g : x \mapsto x/0$. This function cannot be defined stricto sensu, but we can give it a meaning by considering 0 as a limit. Hence $g$ is multivalued and its value is $\{-\infty, +\infty\}$ for every $x$. Hence, $I_1/[0]$ returns $[-\infty, +\infty]$ when $I_1$ is not a point-interval.

Finally, if neither $I_1$ nor $I_2$ are point-intervals, we try to give a meaning to $f(I_1, I_2)$ by an argument of limit-points when possible. For instance $[1, 2]/[0, 1]$ returns $[1, +\infty]$.

As a special exception to these rules, $[0]^{[0]}$ returns $[1]$. 

217
10 Appendix: the Sollya library

10.1 Introduction

The header file of the Sollya library is `sollya.h`. Its inclusion may provoke the inclusion of other header files, such as `gmp.h`, `mpfr.h` or `mpfi.h`.

The library provides a virtual Sollya session that is perfectly similar to an interactive session: global variables such as `verbosity`, `prec`, `display`, `midpointmode`, etc. are maintained and affect the behavior of the library, warning messages are displayed when something is not exact, etc. Please notice that the Sollya library currently is not re-entrant and can only be opened once. A process using the library must hence not be multi-threaded and is limited to one single virtual Sollya session.

In order to get started with the Sollya library, the first thing to do is hence to initialize this virtual session. This is performed with the `sollya_lib_init` function. Accordingly, one should close the session at the end of the program (which has the effect of releasing all the memory used by Sollya). Please notice that Sollya uses its own allocation functions and registers them to GMP using the custom allocation functions provided by GMP. Particular precautions should hence be taken when using the Sollya library in a program that also registers its own functions to GMP: in that case `sollya_lib_init_with_custom_memory_functions` should be used instead of `sollya_lib_init` for initializing the library. This is discussed in Section 10.17.

In the usual case when Sollya is used in a program that does not register allocation functions to GMP, a minimal file using the library is hence the following.

```c
#include <sollya.h>

int main(void) {
    sollya_lib_init();

    /* Functions of the library can be called here */

    sollya_lib_close();
    return 0;
}
```

Suppose that this code is saved in a file called `foo.c`. The compilation is performed as usual without forgetting to link against `libsollya` (since the libraries `libgmp`, `libmpfr` and `libmpfi` are dependencies of Sollya, it might also be necessary to explicitly link against them):

```
~/% cc foo.c -c
~/% cc foo.o -o foo -lsollya -lmpfi -lmpfr -lgmp
```

10.2 Sollya object data-type

The library provides a single data type called `sollya_obj_t` that can contain any Sollya object (a Sollya object is anything that can be stored in a variable within the interactive tool. See Section 5 of the present documentation for details). Please notice that `sollya_obj_t` is in fact a pointer type; this has two consequences:

- NULL is a placeholder that can be used as a `sollya_obj_t` in some contexts. This placeholder is particularly useful as an end marker for functions with a variable number of arguments (see Sections 10.5.5 and 10.15).

- An assignment with the "=" sign does not copy an object but only copies the reference to it. In order to perform a (deep) copy, the `sollya_lib_copy_obj()` function is available.

Except for a few functions for which the contrary is explicitly specified, the following conventions are used:
• A function does not touch its arguments. Hence if \texttt{sollya\_lib\_foo} is a function of the library, a call to \texttt{sollya\_lib\_foo(a)} leaves the object referenced by \texttt{a} unchanged (the notable exceptions to that rule are the functions containing \texttt{build} in their name, e.g., \texttt{sollya\_lib\_build\_foo}).

• A function that returns a \texttt{sollya\_obj\_t} creates a new object (this means that memory is dynamically allocated for that object). The memory allocated for that object should manually be cleared when the object is no longer used and all references to it (on the stack) get out of reach, e.g. on a function return: this is performed by the \texttt{sollya\_lib\_clear\_obj} function. By convenience \texttt{sollya\_lib\_clear\_obj(NULL)} is a valid call, which just does nothing.

In general, except if the user perfectly knows what they are doing, the following rules should be applied (here \texttt{a} and \texttt{b} are C variables of type \texttt{sollya\_obj\_t}, and \texttt{sollya\_lib\_foo} and \texttt{sollya\_lib\_bar} are functions of the library):

• One should never write \texttt{a = b}. Instead, use \texttt{a = sollya\_lib\_copy\_obj(b)}.

• One should never write \texttt{a = sollya\_lib\_foo(a)} because one loses the reference to the object initially referenced by the variable \texttt{a} (which is hence not cleared).

• One should never chain function calls such as, e.g., \texttt{a = sollya\_lib\_foo(sollya\_lib\_bar(b))} (the reference to the object created by \texttt{sollya\_lib\_bar(b)} would be lost and hence not cleared).

• A variable \texttt{a} should never be used twice at the left-hand side of the “=” sign (or as an lvalue in general) without performing \texttt{sollya\_lib\_clear\_obj(a)} in-between.

• In an assignment of the form “\texttt{a = ...}”, the right-hand side should always be a function call (i.e., something like \texttt{a = sollya\_lib\_foo(...);}).

Please notice that \texttt{sollya\_lib\_close()} clears the memory allocated by the virtual Sollya session but not the objects that have been created and stored in C variables. All the \texttt{sollya\_obj\_t} created by function calls should be cleared manually.

We can now write a simple Hello World program using the Sollya library:

```c
#include <sollya.h>

int main(void) {
    sollya_obj_t s1, s2, s;
    sollya_lib_init();

    s1 = sollya_lib_string("Hello ");
    s2 = sollya_lib_string("World!");
    s = sollya_lib_concat(s1, s2);
    sollya_lib_clear_obj(s1);
    sollya_lib_clear_obj(s2);
    sollya_lib_printf("%b\n", s);
    sollya_lib_clear_obj(s);
    sollya_lib_close();
    return 0;
}
```

A universal function allows the user to execute any expression, as if it were given at the prompt of the Sollya tool, and to get a \texttt{sollya\_obj\_t} containing the result of the evaluation: this function is \texttt{sollya\_lib\_parse\_string("some expression here")}. This is very convenient, and indeed, any script written in the Sollya language, could easily be converted into a C program by intensively using \texttt{sollya\_lib\_parse\_string}. However, this should not be the preferred way if efficiency is targeted because (as its name suggests) this function uses a parser to decompose its argument, then constructs intermediate data structures to store the abstract interpretation of the expression, etc. Low-level functions are provided for efficiently creating Sollya objects; they are detailed in the next Section.
10.3 Conventions in use in the library

The library follows some conventions that are useful to remember:

- When a function is a direct transposition of a command or function available in the interactive tool, it returns a `sollya_obj_t`. This is true, even when it would sound natural to return, e.g. an `int`. For instance, `sollya_lib_get_verbosity()` returns a `sollya_obj_t`, whose integer value must then be recovered with `sollya_lib_get_constant_as_int`. This forces the user to declare (and clear afterwards) a temporary `sollya_obj_t` to store the value, but this is the price of homogeneity in the library.

- When a function returns an integer, this integer generally is a boolean in the usual C meaning, i.e. 0 represents false and any non-zero value represents true. In many cases, the integer returned by the function indicates a status of success or failure: the convention is “false means failure” and “true means success”. In case of failure, the convention is that the function did not touch any of its arguments.

- When a function would need to return several things, or when a function would need to return something together with a status of failure or success, the convention is that pointers are given as the first arguments of the function. These pointers shall point to valid addresses where the function will store the results. This can sometimes give obscure signatures, when the function would in principle returns a pointer and actually takes as argument a pointer to a pointer (this typically happens when the function allocates a segment of memory and should return a pointer to that segment of memory).

10.4 Displaying Sollya objects and numerical values

Within the interactive tool, the most simple way of displaying the content of a variable or the value of an expression is to write the name of the variable or the expression, followed by the character ";". As a result, Sollya evaluates the expression or the variable and displays the result. Alternatively, a set of objects can be displayed the same way, separating the objects with commas. In library mode, the same behavior can be reproduced using the function `void sollya_lib_autoprint(sollya_obj_t, ...)`. Please notice that this function has a variable number of arguments: they are all displayed, until an argument equal to `NULL` is found. The `NULL` argument is mandatory, even if only one object shall be displayed (the function has no other way to know if other arguments follow or not). So, if only one argument should be displayed, the correct function call is `sollya_lib_autoprint(arg, NULL)`. Accordingly, if two arguments should be displayed, the function call is `sollya_lib_autoprint(arg1, arg2, NULL)`, etc. The function `void sollya_lib_v_autoprint(sollya_obj_t, va_list)` is the same, but it takes a `va_list` argument instead of a variable number of arguments.

Further, there is another way of printing formatted strings containing Sollya objects, using a `printf`-like syntax. Eight functions are provided, namely:

- `sollya_lib_printf`, `sollya_lib_v_printf`,
- `sollya_lib_fprintf`, `sollya_lib_v_fprintf`,
- `sollya_lib_sprintf`, `sollya_lib_v_sprintf`,
- `sollya_lib_snprintf` and `sollya_lib_v_snprintf`.

Each one of these functions overloads the usual function (respectively, `printf`, `vprintf`, `fprintf`, `vfprintf`, `sprintf`, `vsprintf`, `snprintf` and `vsnprintf`). The full syntax of conversions specifiers supported with the usual functions is handled (please note that the style using ‘$’ — as in `%3$` or `%•3$` — is not handled though. It is not included in the C99 standard anyway). Additionally, the following conversion specifiers are provided:

- `%b`: corresponds to a `sollya_obj_t` argument. There is no precision modifier support.
- `%v`: corresponds to a `mpfr_t` argument. An optional precision modifier can be applied (e.g. `% .5v`).
- `%w`: corresponds to a `mpfi_t` argument. An optional precision modifier can be applied (e.g. `% .5w`).
• \%r: corresponds to a mpq_t argument. There is no precision modifier support.

• \%k: corresponds to a mpz_t argument. There is no precision modifier support.

When one of the above conversion specifiers is used, the corresponding argument is displayed as it would be within the interactive tool: i.e. the way the argument is displayed depends on Sollya environment variables, such as prec, display, midpointmode, etc. When a precision modifier \(n\) is used, the argument is first rounded to a binary precision of roughly \(\log_2(10) \times n\) bits (i.e. roughly equivalent to \(n\) decimal digits) before being displayed. As with traditional printf, the precision modifier can be replaced with * which causes the precision to be determined by an additional int argument.

Flag characters (e.g., '\#', '0', etc.) are allowed but have no effect, except flag character '-' that is supported with its usual meaning of left-aligning the converted value. The full syntax for minimum field width is supported: it can be given directly as an integer in the format string (e.g., %22b) or it can be replaced with *, which causes the field width to be determined by an additional int argument. As usual, a negative field width is taken as a '-' flag followed by a positive width.

As a special (and sometimes convenient) case, \%b accepts that its corresponding sollya_obj_t argument be NULL: in this particular case, the string "NULL" is used in the displayed string. Please notice that, except for the particular case of NULL, the behavior of sollya_lib_printf is completely undefined if the argument of \%b is not a valid Sollya object.

The sollya_lib_printf functions return an integer with the same meaning as the traditional printf functions. It indicates the number of characters that have been output (excluding the final \0 character). Similarly, the conversion specifier \%n can be used, even together with the Sollya conversion specifiers \%b, \%v, \%w, \%r and \%k. The functions sollya_lib_snprintf and sollya_lib_v_snprintf will never write more characters than indicated by their size argument (including the final \0 character). If the output gets truncated due to this limit, they will return the number of characters (excluding the final \0 character) that would have been output if there had not been any truncation. In case of error, all sollya_lib_printf functions return a negative value.

10.5 Creating Sollya objects

Sollya objects conceptually fall into one of five categories: numerical constants (e.g. 1 or 1.5), functional expressions (they might contain numerical constants, e.g., sin(cos(x + 1.5))), other simple objects (intervals, strings, built-in constants such as dyadic, etc.), lists of objects (e.g., [1, "Hello"] and structures (e.g., {.a = 1; .b = "Hello"}).

10.5.1 Numerical constants

Table lists the different functions available to construct numerical constants. A Sollya constant is always created without rounding (whatever the value of global variable prec is at the moment of the function call): a sufficient precision is always allocated so that the constant is stored exactly. All these functions return a constant floating-point number except sollya_lib_constant_from_mpq that may return a constant expression if the value of the rational number given as argument is not exactly representable as a floating-point number at some precision. The returned expression is of the form \(p/q\) in this case.

The objects returned by these functions are newly allocated and copies of the argument. For instance, after the instruction \(a = \text{sollya\_lib\_constant}(b)\), the user will eventually have to clear \(a\) (with sollya\_lib\_clear(a)) and \(b\) (with mpfr\_clear(b)).

The function sollya_lib_constant_from_double (or more conveniently its shortcut SOLLYA_CONST) is probably the preferred way for constructing numerical constants. As the name indicates it, its argument is a double; however, due to implicit casting in C, it is perfectly possible to give an int as argument: it will be converted into a double (without rounding if the integer fits on 53 bits) before being passed to SOLLYA_CONST. On the contrary, the user should be aware of the fact that if decimal non-integer constants are given, C rules of rounding (to double) are applied, regardless of the setting of the Sollya precision variable prec.

10.5.2 Functional expressions

Functional expressions are built by composition of basic functions with constants and the free mathematical variable. Since it is convenient to build such expressions by chaining function calls, the library provides functions that “eat up” their arguments (actually embedding them in a bigger expression). The convention is that functions that eat up their arguments are prefixed by sollya_lib_build_. For the purpose of building expressions, shortcut macros for the corresponding functions exist. They are all listed in Table [2].

It is worth mentioning that, although SOLLYA_X and SOLLYA_PI are used without parentheses (as if they denoted constants), they are in fact function calls that create a new object each time they are used. The absence of parentheses is just more convenient for constructing expressions, such as, e.g. SOLLYA_COS(SOLLYA_X).

For each function of the form sollya_lib_build_function_foo, there exists a function called sollya_lib_foo. There are two differences between them:

- First, sollya_lib_foo does not “eat up” its argument. This can sometimes be useful, e.g., if one has an expression stored in a variable a and one wants to build the expression exp(a) without loosing the reference to the expression represented by a.

- Second, while sollya_lib_build_function_foo mechanically constructs an expression, function sollya_lib_foo also evaluates it, as far as this is possible without rounding.

For instance, after the instructions a = SOLLYA_CONST(0); b = sollya_lib_exp(a); the variable b contains the number 1, whereas it would have contained the expression "exp(0)" if it had been created by b = sollya_lib_build_function_foo(a).

Actually, sollya_lib_foo has exactly the same behavior as writing an expression at the prompt within the interactive tool. In particular, it is possible to give a range as an argument to sollya_lib_foo: the returned object will be the result of the evaluation of function foo on that range by interval arithmetic. In contrast, trying to use sollya_lib_build_function_foo on a range would result in a typing error.

10.5.3 Library functions, library constants and procedure functions

In addition to the mathematical base functions and constants provided by Sollya and listed in the Section above, the user may bind other mathematical functions and constants to Sollya objects under the condition that they can provide code to evaluate these functions or constants. The mechanism behind is similar to the one available in interactive Sollya through the library, libraryconstant and function commands (see Sections 8.94, 8.95 and 8.71).

With the Sollya library, this binding is done through one of the following functions:

- Binding of a (non-constant) mathematical function for which evaluation code is available through a C pointer to a function:
  
  sollya_obj_t sollya_lib_libraryfunction(sollya_obj_t e, 
  char *name, 
  int (*f)(mpfi_t, mpfi_t, int));

  sollya_obj_t sollya_lib_build_function_libraryfunction(sollya_obj_t e,

</tbody>
</table>
These two functions construct a Sollya object representing \( f(e) \) where \( e \) is given as the Sollya object \( e \) and \( f \) is given as the pointer to a function \( f(mpfi_t y, mpfi_t x, int n) \). This code must evaluate the \( n \)-th derivative of \( f \) over the interval \( x \), yielding \( y \).

As usual, `sollya_lib_build_function_libraryfunction` “eats up” the object \( e \), while the function `sollya_lib_libraryfunction` does not.

The `name` argument of the function is taken as a suggestion to the name the Sollya object representing the function should be printed as when displayed. The user may choose to provide `NULL` instead. In any case, upon the binding, the Sollya library will determine a unique displaying name for the function. If it is not yet taken as a name (for some other Sollya object or Sollya keyword), the suggested name will be used. If no suggested name is provided, the name of the dynamic object behind the pointer to the function will be used if it can be determined. Otherwise, a more-or-less random name is used. If the (suggested) base name is already taken, the name is unified appending an underscore and a unique number to it. The `name` argument is never “eaten up”, i.e., it is up to the user to free any memory allocated to that pointer.

- Binding of a mathematical constant for which evaluation code is available through a C pointer to a function:

  ```c
  sollya_obj_t sollya_lib_libraryconstant(char *name,
      void (*c)(mpfr_t, mp_prec_t));
  sollya_obj_t sollya_lib_build_function_libraryconstant(char *name,
      void (*c)(mpfr_t, mp_prec_t));
  ```

  These two functions construct a Sollya object representing the mathematical constant \( c \) for which a pointer to a function \( c(mpfr_t rop, mp_prec_t prec) \) is provided. This code must evaluate the constant to precision \( prec \) and affect the result to \( rop \). See Section 8.95 for details with respect to \( prec \).

  The same remark as above concerning the suggested displaying name of the Sollya object applies for the `name` argument.

- Binding of a mathematical function for which evaluation code is available through a Sollya object representing a Sollya procedure:

  ```c
  sollya_obj_t sollya_lib_procedurefunction(sollya_obj_t e, sollya_obj_t f);
  sollya_obj_t sollya_lib_build_function_procedurefunction(sollya_obj_t e,
      sollya_obj_t f);
  ```

  These two functions construct a Sollya library object representing \( f(e) \) where \( e \) corresponds to the mathematical function (or constant) given with argument \( e \) and where \( f \) is given as a Sollya procedure \( f(x, n, p) \) evaluating the \( n \)-th derivative of \( f \) over the interval \( x \) with precision \( p \). See Section 8.71 concerning details of the arguments of that Sollya procedure.

  As usual, `sollya_lib_build_function_procedurefunction` “eats up” its arguments \( e \) and \( f \) while `sollya_lib_procedurefunction` does not.

  Currently, the only way of constructing a Sollya library object representing a Sollya procedure is to use `sollya_lib_parse_string`.

### 10.5.4 Other simple objects

Other simple objects are created with functions listed in Table 2. The functions with a name of the form `sollya_lib_range_something` follow the same convention as `sollya_lib_constant`: they build a new object from a copy of their argument, and the conversion is always exact, whatever the value of \( prec \).

Please note that in the interactive tool, \( D \) either denotes the discrete mathematical function that maps a real number to its closest double number, or is used as a symbolic constant to indicate that the double format must be used (as an argument of `round` for instance). In the library, they are completely distinct objects, the mathematical function being obtained with `sollya_lib_build_function_double` and the symbolic constant with `sollya_lib_double_obj`. The same holds for other formats (DD, SG, etc.)

</tr>
</tbody>
</table>

*a is a mpfi_t containing the interval [1,3.5]. Conversion is always exact.
*b and c are mpfr_t respectively containing the numbers 1 and 3.5. Conversion is always exact.
10.5.5 Lists

There are actually two kinds of lists: regular lists (such as, e.g., [1, 2, 3]) and semi-infinite lists (such as, e.g., [1, 2...]). With the interactive tool, the ellipsis “...” can sometimes be used as a shortcut to define regular lists, e.g. [1, 2, ..., 10].

In the library, there is no symbol for the ellipsis, and there are two distinct types: one for regular lists and one for semi-infinite lists (called end-elliptic). Defining a regular list with an ellipsis is not possible in the library (except of course with `sollya_lib_parse_string`).

Constructing regular lists is achieved through three functions:

- `sollya_obj_t sollya_lib_list(sollya_obj_t[] L, int n)`: this function returns a new object that is a list the elements of which are copies of L[0], ..., L[n-1].

- `sollya_obj_t sollya_lib_build_list(sollya_obj_t obj1, ...)`: this function accepts a variable number of arguments. The last one must be NULL. It “eats up” its arguments and returns a list containing the objects given as arguments. Since arguments are eaten up, they may be directly produced by function calls, without being stored in variables. A typical use could be

  sollya_lib_build_list(SOLLYA_CONST(1), SOLLYA_CONST(2), SOLLYA_CONST(3), NULL);

- `sollya_obj_t sollya_lib_v_build_list(va_list)`: the same as the previous functions, but with a va_list.

Following the same conventions, end-elliptic lists can be constructed with the following functions:

- `sollya_obj_t sollya_lib_end_elliptic_list(sollya_obj_t[] L, int n)`.

- `sollya_obj_t sollya_lib_build_end_elliptic_list(sollya_obj_t obj1, ...)`.

- `sollya_obj_t sollya_lib_v_build_end_elliptic_list(va_list)`.

10.5.6 Structures

Sollya structures are also available in library mode as any other Sollya object. The support for Sollya structures is however minimal and creating them might seem cumbersome. The only function available to create structures is

```c
int sollya_lib_create_structure(sollya_obj_t *res, sollya_obj_t s, char *name, sollya_obj_t val).
```

This function returns a boolean integer: false means failure, and true means success. Three cases of success are possible. In all cases, the function creates a new object and stores it at the address referred to by res.

- If s is NULL: *res is filled with a structure with only one field. This field is named after the string name and contains a copy of the object val.

- If s is an already existing structure that has a field named after the string name: *res is filled with a newly created structure. This structure is the same as s except that the field corresponding to name contains a copy of val.

- If s is an already existing structure that does not have a field named after the string name: *res is filled with a newly created structure. This structure is the same as s except that it has been augmented with a field corresponding to name and that contains a copy of val.

Please notice that s is not changed by this function: the structure stored in *res is a new one that does not refer to any of the components of s. As a consequence, one should not forget to explicitly clear s as well as *res when they become useless.

2 Users are encouraged to make well-founded feature requests if they feel the need for better support of structures.
10.6 Getting the type of an object

Functions are provided that allow the user to test the type of a Sollya object. They are listed in Table 4. They all return an int interpreted as the boolean result of the test. Please note that from a typing point of view, a mathematical constant and a non-constant functional expression are both functions.

10.7 Recovering the value of a range

If a sollya_obj_t is a range, it is possible to recover the values corresponding to the bounds of the range. The range can be recovered either as an mpfi_t or as two mpfr_t (one per bound). This is achieved with the following conversion functions:
They return a boolean integer: false means failure (i.e., if the sollya_obj_t is not a range) and true means success. These functions follow the same conventions as those of the MPFR and MPFI libraries: the variables res, res_left and res_right must be initialized beforehand, and are used to store the result of the conversion. Also, the functions sollya_lib_get_something_from_range do not change the internal precision of res, res_left and res_right. If the internal precision is sufficient to perform the conversion without rounding, then it is guaranteed to be exact. If, on the contrary, the internal precision is not sufficient, the actual bounds of the range stored in arg will be rounded at the target precision using a rounding mode that ensures that the inclusion property remains valid, i.e. \( \text{arg} \subseteq \text{res} \) (resp. \( \text{arg} \subseteq [\text{res}_\text{left}, \text{res}_\text{right}] \)).

Function int sollya_lib_get_prec_of_range(mp_prec_t *prec, sollya_obj_t arg) stores at *prec a precision that is guaranteed to be sufficient to represent the range stored in arg without rounding. The returned value of this function is a boolean that follows the same convention as above. In conclusion, this is an example of a completely safe conversion:

```c
...  
mp_prec_t prec;
mpfr_t a, b;

if (!sollya_lib_get_prec_of_range(&prec, arg)) {  
sollya_lib_printf("Unexpected error: %b is not a range\n", arg);
}
else {
    mpfr_init2(a, prec);
    mpfr_init2(b, prec);
    sollya_lib_get_bounds_from_range(a, b, arg);
    /* Now [a, b] = arg exactly */
}
...
```

10.8 Recovering the value of a numerical constant or a constant expression

From a conceptual point of view, a numerical constant is nothing but a very simple constant functional expression. Hence there is no difference in Sollya between the way constants and constant expressions are handled. The functions presented in this section allow one to recover the value of such constants or constant expressions into usual C data types.

A constant expression being given, three cases are possible:

- When naively evaluated at the current global precision, the expression always leads to provably exact computations (i.e., at each step of the evaluation, no rounding happens). For instance numerical constants or simple expressions such as \((\exp(0) + 5)/16\) fall in this category.
- The constant expressions would be exactly representable at some precision but this is not straightforward from a naive evaluation at the current global precision. An example would be \(\sin(\pi/3)/\sqrt{3}\) or even \(1 + 2^{-\text{prec} - 10}\).
- Finally, a third possibility is that the value of the expression is not exactly representable at any precision on a binary floating-point number. Possible examples are \(\pi\) or 1/10.

From now on, we suppose that arg is a sollya_obj_t that contains a constant expression (or, as a particular case, a numerical constant). The general scheme followed by the conversion functions is the following: Sollya chooses an initial working precision greater than the target precision. If the value of arg is easily proved to be exactly representable at that precision, Sollya first computes this exact value
and then rounds it to the nearest number of the target format (ties-to-even). Otherwise, Sollya tries to
adapt the working precision automatically in order to ensure that the result of the conversion is one of
both numbers in the target format that are closest to the exact value (a faithful rounding). A warning
message indicates that the conversion is not exact and that a faithful rounding has been performed. In
some cases really hard to evaluate, the algorithm can even fail to find a faithful rounding. In that case,
too, a warning message is emitted indicating that the result of the conversion should not be trusted. Let
us remark that these messages can be caught instead of being displayed and adapted handling can be
provided by the user of the library at each emission of a warning (see Section 10.16).

The conversion functions are the following. They return a boolean integer: false means failure (i.e.,
arg is not a constant expression) and true means success.

- int sollya_lib_get_constant_as_double(double *res, sollya_obj_t arg)
- int sollya_lib_get_constant_as_int(int *res, sollya_obj_t arg): any value too big to
  be represented (this includes ±Inf) is converted to INT_MIN or INT_MAX and a warning is emitted. NaN is converted to 0 with a specific warning.
- int sollya_lib_get_constant_as_int64(int64_t *res, sollya_obj_t arg): any value too
  big to be represented (this includes ±Inf) is converted to INT64_MIN or INT64_MAX and a warning
  is emitted. NaN is converted to 0 with a specific warning.
- int sollya_lib_get_constant_as_uint64(uint64_t *res, sollya_obj_t arg): negative val-
  ues are converted to 0 with a warning. Any value too big to be represented (this includes Inf) is
  converted to UINT64_MAX and a warning is emitted. NaN is converted to 0 with a specific warning.
- int sollya_lib_get_constant_as_mpz(mpz_t res, sollya_obj_t arg): the result of the con-
  version is stored in res. Please note that res must be initialized beforehand. Infinities and NaN
  are converted to 0 with specific warnings.
- int sollya_lib_get_constant_as_mpq(mpq_t res, sollya_obj_t arg): the result of the con-
  version is stored in res. Please note that res must be initialized beforehand. If arg cannot be
  proved to be exactly a floating-point number or the ratio of two floating-point numbers at some
  precision, the function returns false and res is left unchanged.
- int sollya_lib_get_constant(mpfr_t res, sollya_obj_t arg): the result of the conversion
  is stored in res. Please note that res must be initialized beforehand and that its internal precision
  is not modified by the algorithm.

Function int sollya_lib_get_prec_of_constant(mp_prec_t *prec, sollya_obj_t arg) tries to
find a precision that would be sufficient to exactly represent the value of arg without rounding. If it
manages to find such a precision, it stores it at *prec and returns true. If it does not manage to find
such a precision, or if arg is not a constant expression, it returns false and *prec is left unchanged.

In conclusion, here is an example of use for converting a constant expression to a mpfr_t:
... 
mp_prec_t prec;
mpfr_t a;
int test = 0;

test = sollya_lib_get_prec_of_constant(&prec, arg);
if (test) {
    mpfr_init2(a, prec);
    sollya_lib_get_constant(a, arg); /* Exact conversion */
} 
else {
    mpfr_init2(a, 165); /* Initialization at some default precision */
    test = sollya_lib_get_constant(a, arg);
    if (!test) {
        sollya_lib_printf("Error: %b is not a constant expression
", arg);
    }
}
...

10.9 Converting a string from Sollya to C

If arg is a sollya_obj_t that contains a string, that string can be recovered using

    int sollya_lib_get_string(char **res, sollya_obj_t arg).

If arg really is a string, this function allocates enough memory on the heap to store the corresponding string, it copies the string at that newly allocated place, and sets *res so that it points to it. The function returns a boolean integer: false means failure (i.e., arg is not a string) and true means success.

Since this function allocates memory on the heap, this memory should manually be cleared by the user with sollya_lib_free once it becomes useless.

10.10 Recovering the contents of a Sollya list

It is possible to recover the i-th element of a list arg (as one would do using arg[i] withing Sollya) with the following function:

    int sollya_lib_get_element_in_list(sollya_obj_t *res, sollya_obj_t arg, int i).

It returns a boolean integer: false means failure (i.e. arg is not a list or the index is out of range) and true means success. In case of success, a copy of the i-th element of arg is stored at the address referred to by res. Since it is a copy, it should be cleared with sollya_lib_clear_obj when it becomes useless. Please notice that this function works with regular lists as well as with end-elliptic lists, just as within the interactive tool.

Another function allows user to recover all elements of a list in a single call. This function returns a C array of sollya_obj_t objects and has the following signature:

    int sollya_lib_get_list_elements(sollya_obj_t **L, int *n, int *end_ell, sollya_obj_t arg).

Three cases are possible:

- If arg is a regular list of length N, the function allocates memory on the heap for N sollya_obj_t, sets *L so that it points to that memory segment, and copies each of the elements N of arg to (*L)[0], ..., (*L)[N-1]. Finally, it sets *n to N, *end_ell to zero and returns true. A particular case is when arg is the empty list: everything is the same except that no memory is allocated and *L is left unchanged.
• If \( \text{arg} \) is an end-elliptic list containing \( N \) elements plus the ellipsis. The function allocates memory on the heap for \( N \) \text{sollya_obj_t}, sets \(*L\) so that it points to that memory segment, and copies each of the elements \( N \) of \( \text{arg} \) at \((*L)[0], \ldots, (*L)[N-1]\). Finally, it sets \(*n\) to \( N \), \(*\text{end_ell}\) to a non-zero value and returns true. The only difference between a regular list and an end-elliptic list containing the same elements is hence that \(*\text{end_ell}\) is set to a non-zero value in the latter.

• If \( \text{arg} \) is neither a regular nor an end-elliptic list, \(*L\), \(*n\) and \(*\text{end_ell}\) are left unchanged and the function returns false.

In case of success, please notice that \((*L)[0], \ldots, (*L)[N-1]\) should manually be cleared with \text{sollya_lib_clear_obj} when they become useless. Also, the pointer \(*L\) itself should be cleared with \text{sollya_lib_free} since it points to a segment of memory allocated on the heap by Sollya.

10.11 Recovering the contents of a Sollya structure

If \( \text{arg} \) is a \text{sollya_obj_t} that contains a structure, the contents of a given field can be recovered using

\[
\text{int sollya_lib_get_element_in_structure(sollya_obj_t *res, char *name, sollya_obj_t arg).}
\]

If \( \text{arg} \) really is a structure and if that structure has a field named after the string \( \text{name} \), this function copies the contents of that field into the Sollya object \(*\text{res}\). The function returns a boolean integer: false means failure (i.e., if \( \text{arg} \) is not a structure or if it does not have a field named after \( \text{name} \)) and true means success.

It is also possible to get all the field names and their contents. This is achieved through the function

\[
\text{int sollya_lib_get_structure_elements(char ***names, sollya_obj_t **objs, int *n, sollya_obj_t arg).}
\]

If \( \text{arg} \) really is a structure, say with \( N \) fields called “fieldA”, …, “fieldZ”, this functions sets \(*n\) to \( N \), allocates and fills an array of \( N \) strings and sets \(*\text{names}\) so that it points to that segment of memory (hence \((*\text{names})[0]\) is the string “fieldA”, …, \((*\text{names})[N-1]\) is the string “fieldZ”). Moreover, it allocates memory for \( N \) \text{sollya_obj_t}, sets \(*\text{objs}\) so that it points on that memory segment, and copies the contents of each of the \( N \) fields at \((*\text{objs})[0], \ldots, (*\text{objs})[N-1]\). Finally it returns true. If \( \text{arg} \) is not a structure, the function simply returns false without doing anything. Please note that since \(*\text{names}\) and \(*\text{objs}\) point to memory segments that have been dynamically allocated, they should manually be cleared by the user with \text{sollya_lib_free} once they become useless.

10.12 Decomposing a functional expression

If a \text{sollya_obj_t} contains a functional expression, one can decompose the expression tree using the following functions. These functions all return a boolean integer: true in case of success (i.e., if the \text{sollya_obj_t} argument really contains a functional expression) and false otherwise.

• \text{int sollya_lib_get_function_arity(int *n, sollya_obj_t f)}: it stores the arity of the head function in \( f \) at the address referred to by \( n \). Currently, the mathematical functions handled in Sollya are at most dyadic. Mathematical constants are considered as 0-adic functions. The free variable is regarded as the identity function applied to the free variable: its arity is hence 1.

• \text{int sollya_lib_get_head_function(sollya_base_function_t *type, sollya_obj_t f)}: it stores the type of \( f \) at the address referred to by \( \text{type} \). The \text{sollya_base_function_t} is an enum type listing all possible cases (see Table 5).

• \text{int sollya_lib_get_subfunctions(sollya_obj_t f, int *n, \ldots)}: let us denote by \( g_1, \ldots, g_k \) the arguments following the argument \( n \). They must be of type \text{sollya_obj_t}. The function stores the arity of \( f \) at the address referred to by \( n \) (except if \( n \) is NULL, in which case, \text{sollya_lib_get_subfunctions} simply ignores it and goes on). Suppose that \( f \) contains an expression of the form \( f_0(f_1, \ldots, f_k) \) (as a particular case, if \( f \) is just the free variable, it is regarded in this context as the identity function applied to the free variable, so both \( f_0 \) and \( f_1 \) are the...

</table>

For each \(i\) from 1 to \(s\), the expression corresponding to \(f_i\) is stored at the address referred to by \(g_i\), unless one of the \(g_i\) is NULL in which case the function returns when encountering it. In practice, it means that the user should always put NULL as last argument, in order to prevent the case when they would not provide enough variables \(g_i\). They can check afterwards that they provided enough variables by checking the value contained at the address referred to by \(n\). If the user does not put NULL as last argument and do not provide enough variables \(g_i\), the algorithm will continue storing arguments at random places in the memory (on the contrary, providing more arguments than necessary does not harm: useless arguments are simply ignored and left unchanged). In the case when \(f_0\) is a library function, a library constant or a procedure function, and if the user provides a non-NULL argument \(g_t\) after \(g_s\), additional information is returned in the remaining argument:

- If \(f_0\) is a library function, a Sollya object corresponding to the expression \(f_0(x)\) is stored at the address referred to by \(g_t\). This allows the user to get a Sollya object corresponding to function \(f_0\). This object can further be used to evaluate \(f_0\) at points or to build new expressions involving \(f_0\). Please notice that a library function object is not necessarily the result of a call to the \texttt{library} command: it can also be, e.g., the derivative of a function created by a call to \texttt{library}.

- If \(f_0\) is a procedure function, a Sollya object corresponding to the expression \(f_0(x)\) is stored at the address referred to by \(g_t\). The same remarks as above apply.

- If \(f_0\) is a library constant, \(f_0\) itself is stored at the address referred to by \(g_t\). In this particular case, \(t = 1\) and the object referred to by \(g_t\) simply gets a copy of \(f\). This (somewhat useless) mechanism is made only to handle the cases of library functions, procedure functions and library constants in a unified way.

Please note that the objects that have been stored in variables \(g_i\) must manually be cleared once they become useless.

- \texttt{int sollya\_lib\_v\_get\_subfunctions(sollya\_obj\_t f, int *n, va\_list va)}: the same as the previous function, but with a \texttt{va\_list} argument.

- \texttt{int sollya\_lib\_decompose\_function(sollya\_obj\_t f, sollya\_base\_function\_t *type, int *n, ...)}:
  
  this function is a all-in-one function equivalent to using \texttt{sollya\_lib\_get\_head\_function} and \texttt{sollya\_lib\_get\_subfunctions} in only one function call.
• int sollya_lib_v_decompose_function(sollya_obj_t f, sollya_base_function_t *type, int *n, va_list va):

the same as the previous function, but with a va_list.

As an example of use of these functions, the following code returns 1 if \( f \) denotes a functional expression made only of constants (i.e., without the free variable), and returns 0 otherwise:

```c
#include <sollya.h>

/* Note: we suppose that the library has already been initialized */
int is_made_of_constants(sollya_obj_t f) {
  sollya_obj_t tmp1 = NULL;
  sollya_obj_t tmp2 = NULL;
  int n, r, res;
  sollya_base_function_t type;

  r = sollya_lib_decompose_function(f, &type, &n, &tmp1, &tmp2, NULL);
  if (!r) { sollya_lib_printf("Not a mathematical function\n"); res = 0; }
  else if (n >= 3) {
    sollya_lib_printf("Unexpected error: %b has more than two arguments.\n", f);
    res = 0;
  } else {
    switch (type) {
      case SOLLYA_BASE_FUNC_FREE_VARIABLE: res = 0; break;
      case SOLLYA_BASE_FUNC_PI: res = 1; break;
      case SOLLYA_BASE_FUNC_CONSTANT: res = 1; break;
      case SOLLYA_BASE_FUNC_LIBRARYCONSTANT: res = 1; break;
      default:
        res = is_made_of_constants(tmp1);
        if (!res) res = is_made_of_constants(tmp2);
    }
  }

  if (tmp1) sollya_lib_clear_obj(tmp1);
  if (tmp2) sollya_lib_clear_obj(tmp2);
  return res;
}
```

Functions are provided to allow the user to retrieve further information from library function, library constant or procedure function objects:

• int sollya_lib_decompose_libraryfunction(int (**f)(mpfi_t, mpfi_t, int),
  int *deriv, sollya_obj_t *e,
  sollya_obj_t g):

assume that \( g \) represents an expression \( f_0(f_1) \) where \( f_0 \) is a library function. Then, \( f_0 \) is the \( n \)-th derivative (for some \( n \)) of a function provided within Sollya via an external C function \( \text{int func(mpfi_t, mpfi_t, int)} \).

As a result of a call to sollya_lib_decompose_libraryfunction, the value \( n \) is stored at the address referred to by deriv, a pointer to func is stored at the address referred to by \( f \) and a Sollya object representing \( f_1 \) is stored at the address referred to by \( e \). Please notice that the object stored in \( e \) must manually be cleared once it becomes useless. Upon success, a boolean integer representing true is returned. If \( g \) is not a library function object, nothing happens and false is returned.

• int sollya_lib_decompose_procedurefunction(sollya_obj_t *f, int *deriv,
  sollya_obj_t *e, sollya_obj_t g):
assume that \( g \) represents an expression \( f_0(f_1) \) where \( f_0 \) is a procedure function. Then, \( f_0 \) is the \( n \)-th derivative (for some \( n \)) of a function provided within Sollya via a procedure \( \text{proc}(x, n, p) \) \{ ... \}. As a result of a call to \text{sollya\_lib\_decompose\_procedurefunction}, the value \( n \) is stored at the address referred to by \text{deriv}, a Sollya object representing the procedure is stored at the address referred to by \( f \), a Sollya object representing \( f_1 \) is stored at the address referred to by \( e \). Please notice that the objects stored in \( f \) and \( e \) must manually be cleared once they become useless. Upon success, a boolean integer representing true is returned. If \( g \) is not a procedure function object, nothing happens and false is returned.

- \text{int sollya\_lib\_decompose\_libraryconstant}(\text{void (**f)}(\text{mpfr\_t}, \text{mp\_prec\_t}), \text{sollya\_obj\_t c}): assume that \( c \) is a constant provided via an external C function \text{void func(\text{mpfr\_t}, \text{mp\_prec\_t})}. As a result of a call to \text{sollya\_lib\_decompose\_libraryconstant}, a pointer to \text{func} is stored at the address referred to by \( f \) and a boolean integer representing true is returned. Otherwise, nothing happens and false is returned.

10.13 Faithfully evaluate a functional expression

Let us suppose that \( f \) is a functional expression and \( a \) is a numerical value or a constant expression. One of the very convenient features of the interactive tool is that the user can simply write \( f(a) \) at the prompt: the tool automatically adapts its internal precision in order to compute a value that is a faithful rounding (at the current tool precision) of the true value \( f(a) \). Sometimes it does not achieve to find a faithful rounding, but in any case, if the result is not proved to be exact, a warning is displayed explaining how confident one should be with respect to the returned value. This feature is made available within the library with the two following functions:

- \text{sollya\_fp\_result\_t sollya\_lib\_evaluate\_function\_at\_constant\_expression(\text{mpfr\_t res}, \text{sollya\_obj\_t f}, \text{sollya\_obj\_t a}, \text{mpfr\_t *cutoff})},

- \text{sollya\_fp\_result\_t sollya\_lib\_evaluate\_function\_at\_point(\text{mpfr\_t res}, \text{sollya\_obj\_t f}, \text{mpfr\_t a}, \text{mpfr\_t *cutoff})}.

In the former, the argument \( a \) is any \text{sollya\_obj\_t} containing a numerical constant or a constant expression, while in the latter \( a \) is a constant already stored in a \text{mpfr\_t}. These functions store the result in \text{res} and return a \text{sollya\_fp\_result\_t} which is an enum type described in Table 6. In order to understand the role of the \text{cutoff} parameter and the value returned by the function, it is necessary to describe the algorithm in a nutshell:

<table>
<thead>
<tr>
<th><strong>Input:</strong> a functional expression ( f ), a constant expression ( a ), a target precision ( q ), a parameter ( \varepsilon ).</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Choose an initial working precision ( p ).</td>
</tr>
<tr>
<td>2. Evaluate ( a ) with interval arithmetic, performing the computations at precision ( p ).</td>
</tr>
<tr>
<td>3. Replace the occurrences of the free variable in ( f ) by the interval obtained at step 2. Evaluate the resulting expression with interval arithmetic, performing the computations at precision ( p ). This yields an interval ( I = [x, y] ).</td>
</tr>
<tr>
<td>4. Examine the following cases successively (RN denotes rounding to nearest at precision ( q )):</td>
</tr>
<tr>
<td>(a) If RN(( x )) = RN(( y )), set \text{res} to that value and return.</td>
</tr>
<tr>
<td>(b) If ( I ) does not contain any floating-point number at precision ( q ), set \text{res} to one of both floating-point numbers enclosing ( I ) and return.</td>
</tr>
</tbody>
</table>
(c) If $I$ contains exactly one floating-point number at precision $q$, set $\text{res}$ to that number and return.

(d) If all numbers in $I$ are smaller than $\varepsilon$ in absolute value, then set $\text{res}$ to 0 and return.

(e) If $p$ has already been increased many times, then set $\text{res}$ to some value in $I$ and return.

(f) Otherwise, increase $p$ and go back to step 2.

The target precision $q$ is chosen to be the precision of the mpfr_t variable $\text{res}$. The parameter $\varepsilon$ corresponds to the parameter \texttt{cutoff}. The reason why \texttt{cutoff} is a pointer is that, most of the time, the user may not want to provide it, and using a pointer makes it possible to pass \texttt{NULL} instead. So, if \texttt{NULL} is given, $\varepsilon$ is set to 0. If \texttt{cutoff} is not \texttt{NULL}, the absolute value of $\texttt{*cutoff}$ is used as value for $\varepsilon$. Using a non-zero value for $\varepsilon$ can be useful when one does not care about the precise value of $f(a)$ whenever its absolute value is below a given threshold. Typically, if one wants to compute the maximum of $|f(a_1)|$, $\ldots$, $|f(a_n)|$, it is not necessary to spend too much effort on the computation of $|f(a_i)|$ if one already knows that it is smaller than $\varepsilon = \max(|f(a_1)|, \ldots, |f(a_n)|)$.

In the interactive tool, it is also possible to write $f(a)$ when $a$ contains an interval: Sollya performs the evaluation using an enhanced interval arithmetic, e.g., using L’Hopital’s rule to produce finite (yet valid of course) enclosures even in cases when $f$ exhibits removable singularities (for instance $\sin(x)/x$ over an interval containing 0). This feature is achieved in the library with the function

\begin{verbatim}
int sollya_lib_evaluate_function_over_interval(mpfi_t res, sollya_obj_t f, mpfi_t a).
\end{verbatim}

This function returns a boolean integer: false means failure (i.e., $f$ is not a functional expression), in which case $\text{res}$ is left unchanged, and true means success, in which case $\text{res}$ contains the result of the evaluation. The function might succeed, and yet $\text{res}$ might contain something useless such as an unbounded interval or even $[\text{NaN}, \text{NaN}]$ (this happens for instance when $a$ contains points that lie in the interior of the complement of the definition domain of $f$). It is the user’s responsibility to check afterwards whether the computed interval is bounded, unbounded or NaN.

10.14 Name of the free variable

The default name for the free variable is the same in the library and in the interactive tool: it is \texttt{x}. In the interactive tool, this name is automatically changed at the first use of an undefined symbol. Accordingly in library mode, if an object is defined by \texttt{sollya.lib.parse_string} with an expression containing an undefined symbol, that symbol will become the free variable name if it has not already been changed before. But what if one does not use \texttt{sollya.lib.parse_string} (because it is not efficient) but one wants to change the name of the free variable? The name can be changed with \texttt{sollya.lib.name_free_variable("some_name")}.

It is possible to get the current name of the free variable with \texttt{sollya.lib.get_free_variable_name()}. This function returns a \texttt{char *} containing the current name of the free variable. Please note that this \texttt{char *} is dynamically allocated on the heap and should be cleared after its use with \texttt{sollya.lib.free()} (see below).

10.15 Commands and functions

Besides some exceptions, every command and every function available in the Sollya interactive tool has its equivalent (with a very close syntax) in the library. Section 8 of the present documentation gives the library syntax as well as the interactive tool syntax of each commands and functions. The same information is available within the interactive tool by typing \texttt{help some command}. So if one knows the name of a command or function in the interactive tool, it is easy to recover its library name and signature.

There are some commands and functions available in interactive mode which, for syntactical reasons, have a different function name in the Sollya library:
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sollya_fp_obj_no_function</td>
<td>f is not a functional expression.</td>
</tr>
<tr>
<td>Sollya_fp_expression_not_constant</td>
<td>a is not a constant expression.</td>
</tr>
<tr>
<td>Sollya_fp_failure</td>
<td>The algorithm ended up at step (e) and I contained NaN. This typically happens when a is not in the definition domain of f.</td>
</tr>
<tr>
<td>Sollya_fp_cutoff_is_nan</td>
<td>cutoff was not NULL and the value of *cutoff is NaN.</td>
</tr>
<tr>
<td>Sollya_fp_infinity</td>
<td>The algorithm ended up at step (a) with I of the form $[+\infty, +\infty]$ or $[-\infty, -\infty]$. Hence $f(a)$ is proved to be an exact infinity.</td>
</tr>
<tr>
<td>Sollya_fp_proven_exact</td>
<td>The algorithm ended up at step (a) with a finite value and $x = \text{RN}(x) = \text{RN}(y) = y$.</td>
</tr>
<tr>
<td>Sollya_fp_correctly_rounded_proven_inexact</td>
<td>The algorithm ended up at step (b) with a finite value and $\text{res} &lt; x \leq y$ or $x \leq y &lt; \text{res}$.</td>
</tr>
<tr>
<td>Sollya_fp_correctly_rounded</td>
<td>The algorithm ended up at step (a) with a finite value and $x \leq \text{res} \leq y$.</td>
</tr>
<tr>
<td>Sollya_fp_faithful_proven_inexact</td>
<td>The algorithm ended up at step (b) with a finite value and $\text{res} &lt; x \leq y$ or $x \leq y &lt; \text{res}$.</td>
</tr>
<tr>
<td>Sollya_fp_faithful</td>
<td>The algorithm ended up at step (c) with a finite value.</td>
</tr>
<tr>
<td>Sollya_fp_below_cutoff</td>
<td>The algorithm ended up at step (d).</td>
</tr>
<tr>
<td>Sollya_fp_not_faithful_zero_contained_below_threshold</td>
<td>The algorithm ended up at step (e) and I was of the form $[-\delta_1, \delta_2]$ where $0 &lt; \delta_i \ll 1$ (below some threshold of the algorithm). This typically happens when $f(a)$ exactly equals zero, but the algorithm does not manage to prove this exact equality.</td>
</tr>
<tr>
<td>Sollya_fp_not_faithful_zero_contained_not_below_threshold</td>
<td>The algorithm ended up at step (e) with an interval I containing 0 but too large to fall in the above case.</td>
</tr>
<tr>
<td>Sollya_fp_not_faithful_zero_not_contained</td>
<td>The algorithm ended up at step (e) with an interval I that does not contain 0.</td>
</tr>
<tr>
<td>Sollya_fp_not_faithful_infinity_contained</td>
<td>The algorithm ended up at step (e) and (at least) one of the bounds of I was infinite. This typically happens when the limit of $f(x)$ when $x$ goes to $a$ is infinite.</td>
</tr>
</tbody>
</table>

Please notice that this means that the algorithm did not manage to conclude whether the result is exact or not. However, it might have been able to conclude if the working precision had been increased.

In general, this should be considered as a case of failure and the value stored in res might be completely irrelevant.
• The Sollya language construction (obj1)(obj2, obj3, ...) which applies the object obj1 to the objects obj2, obj3, etc. is expressed in the Sollya library through a call to sollya_obj_t sollya_lib_apply(sollya_obj_t obj1, sollya_obj_t obj2, ...) resp. sollya_obj_t sollya_lib_v_apply(sollya_obj_t obj1, sollya_obj_t obj2, va_list).

A particular point is worth mentioning: some functions of the tool such as remez for instance have a variable number of arguments. For instance, one might call remez(exp(x), 4, [0,1]) or remez(1, 4, [0,1], 1/exp(x)). This feature is rendered in the C library by the use of variadic functions (functions with an arbitrary number of arguments), as they are permitted by the C standard. The notable difference is that there must always be an explicit NULL argument at the end of the function call. Hence one can write sollya_lib_remez(a, b, c, NULL) or sollya_lib_remez(a, b, c, d, NULL). It is very easy to forget the NULL argument and to use for instance sollya_lib_remez(a, b, c). This is completely wrong because the memory will be read until a NULL pointer is found. In the best case, this will lead to an error or a result obviously wrong, but it could also lead to subtle, not-easy-to-debug errors. The user is advised to be particularly careful with respect to this point.

Each command or function accepting a variable number of arguments comes in a sollya_lib_v_ version accepting a va_list parameter containing the list of optional arguments. For instance, one might write a function that takes as arguments a function $f$, an interval $I$, optionally a weight function $w$, optionally a quality parameter $q$. That function would display the minimax obtained when approximating $f$ over $I$ (possibly with weight $w$ and quality $q$) by polynomials of degree $n = 2$ to 20. So, that function would get a variable number of arguments (i.e. a va_list in fact) and pass them straight to remez. In that case, one needs to use the v_remez version, as the following code shows:

```c
#include <sollya.h>
#include <stdarg.h>

/* Note: we suppose that the library has already been initialized */
void my_function(sollya_obj_t f, sollya_obj_t I, ...) {
  sollya_obj_t n, res;
  int i;
  va_list va;

  for(i=2;i<=20;i++) {
    n = SOLLYA_CONST(i);
    va_start(va, I);
    res = sollya_lib_v_remez(f, n, I, va);
    sollya_lib_printf("Approximation of degree %b is %b\n", n, res);
    va_end(va);
    sollya_lib_clear_obj(n);
    sollya_lib_clear_obj(res);
  }

  return;
}
```

10.16 Warning messages in library mode

The philosophy of Sollya is “whenever something is not exact, explicitly warn about that”. This is a nice feature since this ensures that the user always perfectly knows the degree of confidence they can have in a result (is it exact? or only faithful? or even purely numerical, without any warranty?) However, it is sometimes desirable to hide some (or all) of these messages. This is especially true in library mode where messages coming from Sollya are intermingled with the messages of the main program. The library hence provides a specific mechanism to catch all messages emitted by the Sollya core and handle each of them specifically: installation of a callback for messages.

Before describing the principle of the message callback, it seems appropriate to recall that several mechanisms are available in the interactive tool to filter the messages emitted by Sollya. These mechanisms are also available in library mode for completeness. When a message is emitted, it has two
characteristics: a verbosity level and an id (a number uniquely identifying the message). After it has been emitted, it passes through the following steps where it can be filtered. If it has not been filtered (and only in this case) it is displayed.

1. If the verbosity level of the message if greater than the value of the environment variable `verbosity`, it is filtered.

2. If the environment variable `roundingwarnings` is set to `off` and if the message informs the user that a rounding occurred, it is filtered.

3. If the id of the message has been registered with the `suppressmessage` command, the message is filtered.

4. If a message callback has been installed and if the message has not been previously filtered, it is handled by the callback, which decides to filter it or to permit its displaying.

A message callback is a function of the form `int my_callback(sollya_msg_t msg, void *data)`. It receives as input an object representing the message and a user-defined pointer. It performs whatever treatment seems appropriate and returns an integer interpreted as a boolean. If the returned value is false, the message is not displayed. If, on the contrary, the returned value is true, the message is displayed as usual. By default, no callback is installed and all messages are displayed. To install a callback, use `sollya_lib_install_msg_callback(my_callback, data)`. The (void *) pointer `data` is arbitrary (it can be NULL) and is simply transmitted as second argument at each call of the callback. It can be used, e.g., to point to a segment of memory where some information should be stored from a call of the callback to another.

Please remember that, if a message is filtered because of one of the three other mechanisms, it will never be transmitted to the callback. Hence, in library mode, if one wants to catch every single message through the callback, one should set the value of `verbosity` to `MAX_INT`, set `roundingwarnings` to `on` (this is the default anyway) and one should not use the `suppressmessage` mechanism.

It is possible to come back to the default behavior, using `sollya_lib_uninstall_msg_callback()`. Please notice that callbacks do not stack over each other: i.e., if some callback `callback1` is installed, and if one installs another one `callback2`, then the effect of `sollya_lib_uninstall_msg_callback()` is to come back to the default behavior, and not to come back to callback `callback1`.

Both `sollya_lib_install_msg_callback` and `sollya_lib_uninstall_msg_callback` return an integer interpreted as a boolean: false means failure and true means success.

It is possible to get the current callback using `sollya_lib_get_msg_callback(cb_ptr, data_ptr)`. This stores the current callback at the address referred to by `cb_ptr` (the type of `cb_ptr` is hence `int (**)(sollya_msg_t, void *)`) and stores the current data pointer at the address referred to by `data_ptr` (which has hence (void **) type). The arguments `cb_ptr` and `data_ptr` can be NULL in which case the corresponding argument is not retrieved (please take care of the difference between `data_ptr` being NULL and `data_ptr` pointing to a (void *) pointer which value is NULL). If no callback is currently installed, the NULL value is stored at the addresses referred to by `cb_ptr` and `data_ptr`.

The type `sollya_msg_t` is indeed a pointer and its content is only accessible during the callback call: it does not make sense to keep it for further use after the callback call. Currently the type has only two accessors:

- `int sollya_lib_get_msg_id(sollya_msg_t msg)` returns an integer that identifies the type of the message. The message types are listed in the file `sollya-messages.h`. Please note that this file not only lists the possible identifiers but only defines meaningful names to each possible message number (e.g., `SOLLYA_MSG_UNDEFINED_ERROR` is an alias for the number 2 but is more meaningful to understand what the message is about). It is recommended to use these names instead of numerical values.

- `char *sollya_lib_msg_to_text(sollya_msg_t msg)` returns a generic string briefly summarizing the contents of the message. Please note that this `char *` is dynamically allocated on the heap and should manually be cleared with `sollya_lib_free` when it becomes useless.

In the future, other accessors could be added (to get the verbosity level at which the message has been emitted, to get data associated with the message, etc.) The developers of Sollya are open to suggestions and feature requests on this subject.
As an illustration let us give a few examples of possible use of callbacks:

**Example 1:** A callback that filters everything.

```c
int hide_everything(sollya_msg_t msg, void *data) {
    return 0;
}
```

**Example 2:** filter everything but the messages indicating that a comparison is uncertain.

```c
int keep_comparison_warnings(sollya_msg_t msg, void *data) {
    switch(sollya_lib_get_msg_id(msg)) {
        case SOLLYA_MSG_TEST_RELIES_ON_FP_RESULT_THAT_IS_NOT_FAITHFUL:
        case SOLLYA_MSG_TEST_RELIES_ON_FP_RESULT:
        case SOLLYA_MSG_TEST_RELIES_ON_FP_RESULT_FAITHFUL_BUT_UNDECIDED:
        case SOLLYA_MSG_TEST_RELIES_ON_FP_RESULT_FAITHFUL_BUT_NOT_REAL:
            return 1;
        default:
            return 0;
    }
}
```

**Example 3:** ensuring perfect silence for a particular function call (uses the callback defined in Example 1).

```c
... int (*old_callback)(sollya_msg_t, void *);
void *old_data;
sollya_lib_get_msg_callback(&old_callback, &old_data);
sollya_lib_install_msg_callback(hide_everything, NULL);
/* Here takes place the function call that must be completely silent */
if (old_callback) sollya_lib_install_msg_callback(old_callback, old_data);
...
```

**Example 4:** using the (void *) data argument to store information from a call to another.

```c
int set_flag_on_problem(sollya_msg_t msg, void *data) {
    switch(sollya_lib_get_msg_id(msg)) {
        case SOLLYA_MSG_DOUBLE_ROUNDING_ON_CONVERSION:
            *((int *)(data)) = 1;
    }
    return 1;
}
...
```

```c
int main() {
    int flag_double_rounding = 0;
    ... sollya_lib_init();
    sollya_lib_install_msg_callback(set_flag_on_problem, &flag_double_rounding);
    ... }
```
More involved examples are possible: for instance, instead of setting a flag, it is possible to keep
in some variable what the last message was. One may even implement a stack mechanism and store
the messages in a stack, in order to handle them later. (Please remember however that sollya_msg_t
is a pointer type and that the sollya_msg_t object received as argument of a callback call has no
more meaning once the callback call returned. If a stack mechanism is implemented it should store
information such as the message ID, or the message text, as given by sollya_lib_get_msg_id and
sollya_lib_msg_to_text, but not the sollya_msg_t object itself.)

10.17 Using Sollya in a program that has its own allocation functions

Sollya uses its own allocation functions: as a consequence, pointers that have been allocated by Sollya
functions must be freed using sollya_lib_free instead of the usual free function. Another consequence
is that Sollya registers its own allocation functions to the GMP library, using the mechanism provided
by GMP, so that GMP also uses Sollya allocation functions behind the scene, when the user performs a
call to, e.g., mpz_init, mpfr_init2, etc.

In general, this is completely harmless and the user might even not notice it. However, this is a
problem if Sollya is used in a program that also uses its own allocation functions and that has already
registered these functions to GMP. Actually:

- If the main program has already registered allocation functions to GMP and if Sollya is naively ini-
tialized with sollya_lib_init(), Sollya will register its own allocation functions, thus overriding
the previously registered functions.

- If the user initializes first Sollya, and then registers its own allocation functions to GMP, the exact
opposite happens: Sollya allocation functions are overridden by those of the user, and this will
likely cause Sollya to crash (or worst, silently behave not reliably).

In order to solve this issue, Sollya provides a chaining mechanism that we are now going to de-
scribe. The idea is the following: suppose that the main program should use a function custom_malloc.
The user should not use mp_set_memory_functions as usual, but should instead initialize Sollya with
the initializing function described above. This will cause Sollya to register an allocation function
sollya_lib_malloc to GMP. This function overloads custom_malloc: when called, it uses custom_malloc
to perform the actual allocation and does nothing else but some internal accounting and verification for
that allocation. To repeat, the actual allocation is done by custom_malloc; hence from the point
of view of the user, the mechanism is completely transparent and equivalent to directly registering
custom_malloc to GMP. The same holds for all other allocation functions: in particular, this is true
for free as well: if a function custom_free is given at the initialization of Sollya, then the function
sollya_lib_free eventually uses custom_free to free the memory.

The initialization function providing this mechanism is:

```c
int sollya_lib_init_with_custom_memory_functions(
    void *(*custom_malloc)(size_t),
    void *(*custom_calloc)(size_t, size_t),
    void *(*custom_realloc)(void *, size_t),
    void (*custom_free)(void *),
    void *(*custom_realloc_with_size)(void *, size_t, size_t),
    void (*custom_free_with_size)(void *, size_t));
```

None of the arguments is mandatory: if the user does not want to provide an argument, they may
use NULL as a placeholder for that argument. In that case, the corresponding Sollya default func-
tion will be used. Indeed, the default initializing function sollya_lib_init() is just an alias to
sollya_lib_init_with_custom_memory_functions(NULL, NULL, NULL, NULL, NULL, NULL).

Please notice, that if custom_malloc is provided, then the function sollya_lib_malloc will be
defined as an overloaded version of custom_malloc. Hence, custom_malloc will eventually be used for
all the allocations performed by Sollya (including the allocation of memory for its own purpose). This
is true also for custom_calloc, custom_realloc and custom_free. However, this is not the case for
custom_realloc_with_size and custom_free_with_size: these functions are only required for the
registration to GMP and are not used by Sollya itself (except of course when Sollya allocates function
through a call to a GMP, MPFR or MPFI function). Thus, to sum up:
• If the user only wants to register their own functions to GMP through Sollya, they only need to provide `custom_malloc`, `custom_realloc_with_size` and `custom_free_with_size` at the initialization of Sollya (actually an overloaded version will be registered to GMP but this is transparent for the user, as explained above).

• If the user also wants Sollya to use their custom allocation functions for all allocations of memory by Sollya, then they also need to provide `custom_calloc`, `custom_realloc` and `custom_free`.

Of course, even if the user registers `custom_malloc`, `custom_free`, etc., at the initialization of Sollya, they stay free to use them for their own allocation needs: only allocations performed by GMP (and consequently MPFR and MPFI) and allocations performed by Sollya have to use the chaining mechanism. However, for the convenience of the user, the library also provides access to the allocation functions of Sollya. They are the following:

- `void sollya_lib_free(void *)`
- `void *sollya_lib_malloc(size_t)`
- `void *sollya_lib_calloc(size_t, size_t)`
- `void *sollya_lib_realloc(void *, size_t)`.

No access to the overloaded version of `custom_realloc_with_size` and `custom_free_with_size` is provided, but if the user really wants to retrieve them, they can do it with `mp_get_memory_functions` since they are registered to GMP.
